

1 **I. Introduction and Summary of Recommendations**

2 **Q. Please state your name, occupation, and business address.**

3 A. My name is Samuel C. Hadaway. I am a Principal in FINANCO, Inc., Financial  
4 Analysis Consultants, 3520 Executive Center Drive, Austin, Texas 78731.

5 **Q. On whose behalf are you testifying?**

6 A. I am testifying on behalf of PacifiCorp (the Company).

7 **Q. Please state your educational background and describe your professional  
8 training and experience.**

9 A. I have an economics degree from Southern Methodist University and MBA and  
10 Ph.D. degrees in finance from the University of Texas at Austin (UT Austin). I  
11 am presently an adjunct professor in the McCombs School of Business at UT  
12 Austin. I have taught economics and finance courses at several universities, and I  
13 have conducted research and directed graduate students writing in these areas. I  
14 was previously Director of the Economic Research Division at the Public Utility  
15 Commission of Texas, where I supervised the Commission's finance, economics,  
16 and accounting staff and served as the Commission's chief financial witness in  
17 electric and telephone utility rate cases. In various utility conferences I have  
18 taught courses on cost of capital, capital structure, utility financial condition, and  
19 cost allocation and rate design methods. I have made presentations before the  
20 New York Society of Security Analysts, the National Rate of Return Analysts  
21 Forum, and various other professional and legislative groups. I have served on  
22 the board of directors and as a vice president of the Financial Management  
23 Association.

1 A list of my publications and testimony I have given before various  
2 regulatory bodies and in state and federal courts is contained in my resume, which  
3 is included as Exhibit No.\_\_(SCH-2).

4 **Q. What is the purpose of your present testimony?**

5 A. The purpose of my testimony is to estimate PacifiCorp's market required rate of  
6 return on equity (ROE).

7 **Q. Please outline and describe the testimony you will present.**

8 A. My testimony is divided into four sections. Following this introduction, in  
9 Section II, I review various methods for estimating the cost of equity capital. In  
10 this section, I discuss the discounted cash flow (DCF) model as well as risk  
11 premium methods and other approaches often used to estimate the cost of capital.  
12 In Section III, I review general capital market costs and conditions and discuss  
13 recent developments in the electric utility industry that may affect the cost of  
14 capital. In Section IV, I present the details of my cost of equity studies and  
15 provide a summary table of my ROE results.

16 **Q. Please summarize your cost of equity studies and state your ROE  
17 recommendation.**

18 A. My ROE estimate is based on alternative versions of the constant growth and  
19 multistage growth DCF model and is confirmed by my risk premium analysis and  
20 my review of economic conditions expected to prevail during the rate effective  
21 period. PacifiCorp's cost of equity cannot be estimated directly from its own  
22 market data because PacifiCorp is a wholly owned subsidiary of ScottishPower.  
23 As such, PacifiCorp does not have publicly traded common stock or other

1 independent market data that would be required to estimate its cost of equity  
2 directly. I apply the DCF models to a conservative sample of electric utilities  
3 selected from the *Value Line Investment Survey*. To be included in my  
4 comparable company group, companies were required to have a single-A bond  
5 rating by either Moody's or Standard and Poor's, to derive at least 70 percent of  
6 revenues from regulated utility sales, to have consistent financial records not  
7 affected by recent mergers or restructuring, and to have a consistent dividend  
8 record as required by the DCF model.

9 To test my DCF results, I provide a bond-yield-plus-equity risk-premium  
10 analysis based on Moody's single-A cost of utility debt. This is the appropriate  
11 basis for the risk premium analysis, since PacifiCorp's senior debt is rated single-  
12 A by both Moody's and Standard & Poor's (A3 by Moody's and A- by S&P).

13 I also present S&P's forecasts for economic growth and for expected  
14 interest rates over the next year. The S&P forecasts indicate improving economic  
15 conditions and rising interest rates during the rate effective period. Under current  
16 economic, market, and electric utility industry conditions, this combination  
17 approach is the most appropriate for estimating the fair cost of equity capital. The  
18 data sources and the details of my rate of return analysis are contained in Exhibit  
19 Nos.\_\_(SCH-3) through \_\_(SCH-5).

20 My DCF analysis indicates that an ROE range of 10.7 percent to 11.2  
21 percent is appropriate. As I will explain in more detail later, the lower end of my  
22 DCF results, from the traditional constant growth DCF model at 9.3 percent to 9.5  
23 percent, fails to meet basic checks of reasonableness and, therefore, those results

1 are not included in the estimated DCF range. The traditional constant growth  
2 DCF results do not reasonably reflect the current cost of equity, because its results  
3 depend on historically low dividend yields and pessimistic analysts' growth  
4 forecasts, which do not adequately reflect current consensus expectations for  
5 increasing capital costs. My risk premium analysis serves as a check of  
6 reasonableness for the DCF results. That analysis indicates an ROE of 11.0  
7 percent, with other risk premium approaches indicating ROEs as high as 11.8  
8 percent.

9 Because recent historical data have a significant effect in the traditional  
10 constant growth DCF model, and because recent data appear to represent historic  
11 lows in the economic cycle, those data should not be the primary basis for setting  
12 PacifiCorp's allowed rate of return. In my DCF analysis, I offer several  
13 alternatives for estimating the long-term DCF growth rate.

14 Based on the combination of my quantitative model results, and my  
15 review of the current economic, market, and electric utility industry conditions, I  
16 estimate PacifiCorp's fair cost of equity capital at 11.125 percent. This estimate  
17 is consistent with capital market trends and projections and is a reasonable  
18 estimate of capital market costs that will prevail while the rates from this case are  
19 in effect.

20 **II. Estimating the Cost of Equity**

21 **Q. What is the purpose of this section of your testimony?**

22 A. The purpose of this section is to present a general definition of the cost of equity  
23 and to compare the strengths and weaknesses of several of the most widely used

1 methods for estimating the cost of equity. Estimating the cost of equity is  
2 fundamentally a matter of informed judgment. The various models provide a  
3 concrete link to actual capital market data and assist with defining the various  
4 relationships that underlie the ROE estimation process.

5 **Q. Please define the term “cost of equity capital” and provide an overview of the**  
6 **cost estimation process.**

7 A. The cost of equity capital is the profit or rate of return that equity investors expect  
8 to receive. In concept it is no different than the cost of debt or the cost of  
9 preferred stock. The cost of equity is the rate of return that common stockholders  
10 expect, just as interest on bonds and dividends on preferred stock are the returns  
11 that investors in those securities expect. Equity investors expect a return on their  
12 capital commensurate with the risks they take and consistent with returns that  
13 might be available from other similar investments. Unlike returns from debt and  
14 preferred stocks, however, the equity return is not directly observable in advance  
15 and, therefore, it must be estimated or inferred from capital market data and  
16 trading activity.

17 An example helps to illustrate the cost of equity concept. Assume that an  
18 investor buys a share of common stock for \$20 per share. If the stock’s expected  
19 dividend during the coming year is \$1.00, the expected dividend yield is 5 percent  
20 ( $\$1.00 / \$20 = 5.0$  percent). If the stock price is also expected to increase to  
21 \$21.20 after one year, this \$1.20 expected gain adds an additional 6 percent to the  
22 expected total rate of return ( $\$1.20 / \$20 = 6$  percent). Therefore, buying the  
23 stock at \$20 per share, the investor expects a total return of 11 percent: 5 percent

1 dividend yield, plus 6 percent price appreciation. In this example, the total  
2 expected rate of return at 11 percent is the appropriate measure of the cost of  
3 equity capital, because it is this rate of return that caused the investor to commit  
4 the \$20 of equity capital in the first place. If the stock were riskier, or if expected  
5 returns from other investments were higher, investors would have required a  
6 higher rate of return from the stock, which would have resulted in a lower initial  
7 purchase price in market trading.

8 Each day, market rates of return and prices change to reflect new investor  
9 expectations and requirements. For example, when interest rates on bonds and  
10 savings accounts rise, utility stock prices usually fall. This is true, at least in part,  
11 because higher interest rates on these alternative investments make utility stocks  
12 relatively less attractive, which causes utility stock prices to decline in market  
13 trading. This competitive market adjustment process is quick and continuous, so  
14 that market prices generally reflect investor expectations and the relative  
15 attractiveness of one investment versus another. In this context, to estimate the  
16 cost of equity one must apply informed judgment about the relative risk of the  
17 Company in question and knowledge about the risk and expected rate of return  
18 characteristics of other available investments as well.

19 **Q. How does the market account for risk differences among the various**  
20 **investments?**

21 A. Risk-return tradeoffs among capital market investments have been the subject of  
22 extensive financial research. Literally dozens of textbooks and hundreds of  
23 academic articles have addressed the issue. Generally, such research confirms the

1 common sense conclusion that investors will take additional risks only if they  
2 expect to receive a higher rate of return. Empirical tests consistently show that  
3 returns from low risk securities, such as U.S. Treasury bills, are the lowest; that  
4 returns from longer-term Treasury bonds and corporate bonds are increasingly  
5 higher as risks increase; and generally, returns from common stocks and other  
6 more risky investments are even higher. These observations provide a sound  
7 theoretical foundation for both the DCF and risk premium methods for estimating  
8 the cost of equity capital. These methods attempt to capture the well-founded  
9 risk-return principle and explicitly measure investors' rate of return requirements.

10 **Q. Can you illustrate the capital market risk-return principle that you just**  
11 **described?**

12 A. Yes. The following graph depicts the risk-return relationship that has become  
13 widely known as the Capital Market Line (CML). The CML offers a graphical  
14 representation of the capital market risk-return principle. The graph is not meant  
15 to illustrate the actual expected rate of return for any particular investment, but  
16 merely to illustrate in a general way the risk-return relationship.

1

## Risk-Return Tradeoffs

2                   As a continuum, the CML can be viewed as an available opportunity set  
 3 for investors. Those investors with low risk tolerance or investment objectives  
 4 that mandate a low risk profile should invest in assets depicted in the lower left-  
 5 hand portion of the graph. Investments in this area, such as Treasury bills and  
 6 short-maturity, high quality corporate commercial paper, offer a high degree of  
 7 investor certainty. In nominal terms (before considering the potential effects of  
 8 inflation), such assets are virtually risk-free.

9                   Investment risks increase as one moves up and to the right along the CML.  
 10 A higher degree of uncertainty exists about the level of investment value at any  
 11 point in time and about the level of income payments that may be received.  
 12 Among these investments, long-term bonds and preferred stocks, which offer

1 priority claims to assets and income payments, are relatively low risk, but they are  
2 not risk-free. The market value of long-term bonds, even those issued by the U.S.  
3 Treasury, often fluctuates widely when government policies or other factors cause  
4 interest rates to change.

5 Farther up the CML continuum, common stocks are exposed to even more  
6 risk, depending on the nature of the underlying business and the financial strength  
7 of the issuing corporation. Common stock risks include market-wide factors,  
8 such as general changes in capital costs, as well as industry and company specific  
9 elements that may add further to the volatility of a given company's performance.  
10 As I will illustrate in my risk premium analysis, common stocks typically are  
11 more volatile (have higher risk) than high quality bond investments and,  
12 therefore, they reside above and to the right of bonds on the CML graph. Other  
13 more speculative investments, such as stock options and commodity futures  
14 contracts, offer even higher risks (and higher potential returns). The CML's  
15 depiction of the risk-return tradeoffs available in the capital markets provides a  
16 useful perspective for estimating investors' required rates of return.

17 **Q. How is the fair rate of return in the regulatory process related to the**  
18 **estimated cost of equity capital?**

19 A. The regulatory process is guided by fair rate of return principles established in the  
20 U.S. Supreme Court cases, *Bluefield Water Works* and *Hope Natural Gas*:

21 A public utility is entitled to such rates as will permit it to earn a  
22 return on the value of the property which it employs for the  
23 convenience of the public equal to that generally being made at the  
24 same time and in the same general part of the country on  
25 investments in other business undertakings which are attended by  
26 corresponding risks and uncertainties; but it has no constitutional

1 right to profits such as are realized or anticipated in highly  
2 profitable enterprises or speculative ventures. *Bluefield*  
3 *Waterworks & Imp. Co. v. West Virginia Public Service*  
4 *Commission*, 262 U.S. 679, 692-693 (1923).

5 From the investor or company point of view, it is important that  
6 there be enough revenue not only for operating expenses, but also  
7 for the capital costs of the business. These include service on the  
8 debt and dividends on the stock. By that standard the return to the  
9 equity owner should be commensurate with returns on investments  
10 in other enterprises having corresponding risks. That return,  
11 moreover, should be sufficient to assure confidence in the financial  
12 integrity of the enterprise, so as to maintain its credit and to attract  
13 capital. *Federal Power Comm. v. Hope Natural Gas Co.*, 320 U.S.  
14 591, 603 (1944).

15 Based on these principles, the fair rate of return should closely parallel  
16 investor opportunity costs as discussed above. If a utility earns its market  
17 cost of equity, neither its stockholders nor its customers should be  
18 disadvantaged.

19 **Q. What specific methods and capital market data are used to evaluate the cost**  
20 **of equity?**

21 A. Techniques for estimating the cost of equity normally fall into three groups:  
22 comparable earnings methods, risk premium methods, and DCF methods.  
23 Comparable earnings methods have evolved over time. The original comparable  
24 earnings methods were based on book accounting returns. This approach  
25 developed ROE estimates by reviewing accounting returns for unregulated  
26 companies thought to have risks similar to those of the regulated company in  
27 question. These methods generally have been rejected because they assume that  
28 the unregulated group is earning its actual cost of capital, and that its equity book  
29 value is the same as its market value. In most situations these assumptions are not

1 valid and, therefore, accounting-based methods generally do not provide reliable  
2 cost of equity estimates.

3 More recent comparable earnings methods are based on historical stock  
4 market returns rather than book accounting returns. While this approach has  
5 some merit, it too has been criticized because there can be no assurance that  
6 historical returns actually reflect current or future market requirements. Also, in  
7 practical application, earned market returns tend to fluctuate widely from year to  
8 year. For these reasons, a current cost of equity estimate (based on the DCF  
9 model or a risk premium analysis) is usually required.

10 The second set of estimation techniques is grouped under the heading of  
11 risk premium methods. These methods begin with currently observable market  
12 returns, such as yields on government or corporate bonds, and add an increment to  
13 account for the additional equity risk. The capital asset pricing model (CAPM)  
14 and arbitrage pricing theory (APT) model are more sophisticated risk premium  
15 approaches. The CAPM and APT methods estimate the cost of equity directly by  
16 combining the “risk-free” government bond rate with explicit risk measures to  
17 determine the risk premium required by the market. Although these methods are  
18 widely used in academic cost of capital research, their additional data  
19 requirements and their potentially questionable underlying assumptions have  
20 detracted from their use in most regulatory jurisdictions. .

21 The DCF model is the most widely used approach in regulatory  
22 proceedings. Like the risk premium method, the DCF model has a sound basis in  
23 theory, and many argue that it has the additional advantage of simplicity. I will

1 describe the DCF model in detail below, but in essence its estimate of ROE is  
2 simply the sum of the expected dividend yield and the expected long-term  
3 dividend (or price) growth rate. While dividend yields are readily available, long-  
4 term growth estimates are more difficult to obtain. Because the constant growth  
5 DCF model requires very long-term growth estimates (technically to infinity),  
6 some argue that its application is subjective and that more explicit multistage  
7 growth DCF models are preferred. In the final analysis, ROE estimates are  
8 subjective and should be based on sound, informed judgment. To accomplish this  
9 task, I apply several versions of the DCF and risk premium models, which results  
10 in an ROE range that I believe brackets the fair cost of equity capital.

11 **Q. Please explain the DCF model.**

12 A. The DCF model is predicated on the concept, or in fact the definition, that a  
13 stock's price represents the present value of all future cash flows expected from  
14 the stock. In the most general form, the model is expressed in the following  
15 formula:

$$16 \quad P_0 = D_1/(1+k) + D_2/(1+k)^2 + \dots + D_\infty/(1+k)^\infty \quad (1)$$

17 where  $P_0$  is today's stock price;  $D_1$ ,  $D_2$ , etc. are all expected future dividends and  
18  $k$  is the discount rate, or the investor's required rate of return on equity.

19 Equation (1) is a routine present value calculation with the difficult data  
20 requirement of estimating all future dividends. (As a practical matter, the present  
21 value of dividends expected in the very distant future is typically insignificant,  
22 and operationally the DCF model can be reasonably estimated by discounting a  
23 long, but finite dividend stream, or with the assumption that the stock will be sold

1 for some estimated price in the future.)

2 Under the additional assumption that dividends are expected to grow at a  
3 constant rate “g,” equation (1) can be solved for k and rearranged into the simple  
4 form:

$$5 \quad k = D_1/P_0 + g \quad (2)$$

6 Equation (2) is the familiar constant growth DCF model for cost of equity  
7 estimation, where  $D_1/P_0$  is the expected dividend yield and g is the long-term  
8 expected dividend growth rate.

9 Under circumstances when growth rates are expected to fluctuate or when  
10 future growth rates are highly uncertain, the constant growth model may be  
11 questionable, and explicit changing growth estimates may be required. Although  
12 the DCF model itself is still valid (equation (1) is mathematically correct), under  
13 the assumption of fluctuating growth the simplified form of the model must be  
14 modified to capture market expectations accurately.

15 **Q. How is the DCF model applied when the growth rates fluctuate?**

16 A. When growth rates are expected to fluctuate, the more general version of the  
17 model represented in equation (1) should be solved explicitly over a finite  
18 “transition” period while uncertainty prevails. The constant growth version of the  
19 model can then be applied after the transition period, under the assumption that  
20 more stable conditions will prevail in the future. There are two alternatives for  
21 dealing with the nonconstant growth transition period.

22 Under the “Market Price” version of the DCF model, equation (1) is  
23 written in a slightly different form:

$$1 \quad P_0 = D_1/(1+k) + D_2/(1+k)^2 + \dots + P_T/(1+k)^T \quad (3)$$

2 where the variables are the same as in equation (1) except that  $P_T$  is the estimated  
 3 Market Price at the end of the transition period T. Under the assumption that  
 4 constant growth resumes after the transition period, the price  $P_T$  is then expected  
 5 to be based on constant growth assumptions. As with the general form of the  
 6 DCF model in equation (1), in the Market Price approach the current stock price  
 7 ( $P_0$ ) is the present value of expected cash inflows, but the cash flows are  
 8 comprised of dividends and an ultimate selling price for the stock. The estimated  
 9 cost of equity,  $k$ , is just the rate of return that investors would expect if they  
 10 bought the stock at today's price, held it and received dividends through the  
 11 transition period (until period T), and then sold it for price  $P_T$ .

12 Under the "Multistage" growth DCF approach, equation (1) is expanded to  
 13 incorporate two or more growth rate periods, with the assumption that a  
 14 permanent constant growth rate can be estimated for some point in the future:

$$15 \quad P_0 = D_0(1+g_1)/(1+k) + \dots + D_0(1+g_2)^n/(1+k)^n +$$

$$16 \quad \dots + D_0(1+g_T)^{(T+1)}/(k-g_T) \quad (4)$$

17 where the variables are the same as in equation (1), but  $g_1$  represents the growth  
 18 rate for the first period,  $g_2$  for a second period, and  $g_T$  for the period from year T  
 19 (the end of the transition period) to infinity. The first two growth rates are  
 20 estimates of fluctuating growth over "n" years (typically 5 or 10 years), and  $g_T$  is  
 21 a constant growth rate assumed to prevail forever after year T.

22 Although less convenient for exposition purposes, the nonconstant growth  
 23 models are based on the same valid capital market assumptions as the constant

1 growth version. The nonconstant growth approach simply requires more explicit  
2 data inputs and more work to solve for the discount rate,  $k$ . Fortunately, the  
3 required data are generally available from investment and economic forecasting  
4 services, and computer algorithms can easily produce the required solutions.  
5 Both constant and nonconstant growth DCF analyses are presented in the  
6 following section.

7 **Q. Please explain the risk premium methodology.**

8 A. Risk premium methods are based on the assumption that equity securities are  
9 riskier than debt and, therefore, that equity investors require a higher rate of  
10 return. This basic premise is well supported by legal and economic distinctions  
11 between debt and equity securities, and it is widely accepted as a fundamental  
12 capital market principle. For example, debt holders' claims to the earnings and  
13 assets have priority over all claims of equity investors. The contractual interest on  
14 mortgage debt generally must be paid in full before any dividends can be paid to  
15 shareholders, and secured mortgage claims must be fully satisfied before any  
16 assets can be distributed to shareholders in bankruptcy. Also, the guaranteed,  
17 fixed-income nature of interest payments on debt makes year-to-year returns from  
18 bonds typically more stable than capital gains and dividend payments on stocks.  
19 All these factors support the proposition that stockholders are exposed to more  
20 risk and that shareholders should reasonably expect a positive equity risk  
21 premium.

22

1 **Q. Are risk premium estimates of the cost of equity consistent with other**  
2 **current capital market costs?**

3 A. Yes. The risk premium approach is especially useful because it is founded on  
4 current market interest rates, which are directly observable. This feature assures  
5 that risk premium estimates of the cost of equity begin with a sound basis, which  
6 is tied directly to current capital market costs.

7 **Q. Is there similar consensus about how risk premium data should be**  
8 **employed?**

9 A. No. In regulatory practice, there is often considerable debate about how risk  
10 premium data should be interpreted and used. Since the analyst's basic task is to  
11 gauge investors' required returns on long-term investments, some argue that the  
12 estimated equity spread should be based on the longest possible time period.  
13 Others argue that market relationships between debt and equity from several  
14 decades ago are irrelevant and that recent debt-equity observations should be  
15 given more weight in estimating investor requirements. There is no consensus on  
16 this issue. Since analysts cannot observe or measure investors' actual  
17 expectations, it is not possible to know exactly how such expectations are formed  
18 or, therefore, exactly what time period is most appropriate in a risk premium  
19 analysis.

20 The important question to answer is the following: "What rate of return  
21 should equity investors reasonably expect relative to returns currently available  
22 from long-term bonds?" The risk premium studies and analyses I discuss in  
23 Section IV address this question. My risk premium recommendation is based on

1 an intermediate position that avoids some of the problems and concerns that have  
2 been expressed about both very long and very short periods of analysis with the  
3 risk premium model.

4 **Q. Please summarize your discussion of cost of equity estimation techniques.**

5 A. Estimating the cost of equity is a controversial issue in utility ratemaking.  
6 Because actual investor requirements are not directly observable, analysts have  
7 developed several methods to assist in the process. The comparable earnings  
8 method is the oldest but perhaps least reliable. Its use of accounting rates of  
9 return, or even historical market returns, may or may not reflect current investor  
10 requirements. Differences in accounting methods among companies and issues of  
11 comparability also detract from this approach.

12 The DCF and market-based risk premium methods are more widely  
13 accepted in regulatory practice. I believe that a combination of the DCF model  
14 and a review of risk premium data provide the most reliable approach. While the  
15 DCF model requires judgment about future growth rates, the dividend yield  
16 portion of the model is straightforward, and the model's results are generally  
17 consistent with actual capital market behavior. For these reasons, I rely  
18 principally upon the DCF model, and I test the reasonableness of the DCF results  
19 by comparing to market-based risk premiums.

20 **III. Fundamental Factors that Affect the Cost of Equity Capital**

21 **Q. What is the purpose of this section of your testimony?**

22 A. The purpose of this section is to review recent and future capital market costs and  
23 conditions as well as industry- and company-specific factors that should be

1 reflected in the cost of equity estimate.

2 **Q. What has been the recent experience in the U.S. capital markets?**

3 A. Exhibit No.\_\_(SCH-3), page 1 provides a review of annual interest rates and  
4 rates of inflation in the U.S. economy over the past ten years. During that time  
5 period, inflation and capital market costs have declined and, generally, have been  
6 lower than rates that prevailed in the previous decade. Inflation, as measured by  
7 the Consumer Price Index, has remained at historically low levels not seen  
8 consistently since the early 1960s. Until the first quarter of 2004, the uneven pace  
9 of economic recovery kept consumer price increases in check and resulted in the  
10 lowest interest rates in four decades. Since March 2004, however, improving  
11 economic growth and concerns about renewed inflation have led to fluctuating  
12 interest rates. Estimates for the next 12 months are for continued economic  
13 growth and further interest rate increases.

14 Exhibit No.\_\_(SCH-3), page 2 provides a summary of Moody's Average  
15 Utility and Single-A Utility Bond Yields. For the most recent three months ended  
16 March 2005, Moody's Average Utility Rate was 5.79 percent and the Single-A  
17 Utility Rate was 5.70 percent.

18 Exhibit No.\_\_(SCH-3), page 3 provides S&P's *Economic Trends &*  
19 *Projections* for March 17, 2005. The forecast data show clear expectations for  
20 continuing economic growth, with growth in real Gross Domestic Product (GDP)  
21 for 2005 projected at 3.8 percent. This projected GDP growth rate compares to  
22 rates of less than 2 percent in 2001, 2.4 percent for 2002, and 3 percent for 2003.  
23 Consistent with sound economic conditions, S&P also forecasts that the

1 unemployment rate will drop to 5.1 percent and that interest rates will rise an  
2 additional 90 basis points (0.9 percent) from current levels. The 10-year Treasury  
3 Note is projected to increase from its current level of about 4.3 percent to 5.2  
4 percent by the 2nd quarter of 2006. Long-term Treasury Bonds are projected to  
5 increase from current levels of about 4.8 percent to 5.7 percent, and Corporate  
6 Bonds are projected to increase from current levels of about 5.3 percent to 6.2  
7 percent. These increasing interest rate trends offer important perspective for  
8 judging the cost of capital in the present case.

9 Exhibit No.\_\_(SCH-3), page 4, provides economic and interest rate  
10 projections from *Value Line's* latest long-term forecast. For 2006, *Value Line's*  
11 interest rate projections are similar to S&P's. The *Value Line* forecasts also  
12 shows that rates are expected to continue increasing for the next several years.

13 **Q. What are the key factors currently affecting electric utility investments?**

14 A. Although electric utilities are returning to their core businesses and are expected  
15 to see more stable results over the next several years, expectations for utility  
16 stocks are negative due to projections for higher interest rates. In its most recent  
17 edition covering electric utilities, *Value Line* reflected its concerns:

18 **Investment Advice**

19 Many of the utility stocks in this issue are trading at or near  
20 their 52-week highs. But if *Value Line's* projection of rising  
21 interest rates is on target, share prices of these equities may  
22 decline. Too, the industry's Timeliness rank remains near the  
23 bottom of all industries we follow. At this juncture, more  
24 attractive investments are available elsewhere. (*Value Line*  
25 *Investment Survey*, April 1, 2005, p. 695.)

1 Expectations for rising interest rates also make it more difficult to estimate  
2 utilities' cost of capital. In this environment of increased interest rates, the  
3 traditional DCF model does not produce reasonable cost of capital estimates.

4 **Q. Is PacifiCorp affected by these same market uncertainties and concerns?**

5 A. Yes. To varying extents, all utilities are affected by market uncertainties and the  
6 changes affecting the energy industry. PacifiCorp's 2004 IRP projects the need  
7 for substantial new generation resources. Demands to expand the transmission  
8 and distribution resources are also growing rapidly. This situation drives  
9 increased capital investment needs. In this setting it is essential for PacifiCorp to  
10 have a sound earnings base to support its capital investment needs.

11 **Q. How does the Company's proposal in this case to implement a power cost  
12 adjustment (PCA) mechanism affect your analysis?**

13 A. It does not change my analysis. First, virtually all of the comparable companies  
14 used in my comparable company group of electric utilities have some form of  
15 power cost recovery mechanism. If PacifiCorp is successful in this proceeding in  
16 obtaining approval to implement a PCA mechanism, the Company's Washington  
17 operations will simply be brought into line with the risk profile of the comparable  
18 companies. Second, while the Commission in the past has suggested that  
19 implementation of a PCA mechanism should be accompanied by a reduction in  
20 the allowed ROE, such a downward adjustment is unwarranted. Given the  
21 increased volatility in power markets and other circumstances described in Mr.  
22 Widmer's and Ms. Omohundro's testimony, the issue does not involve a simple  
23 re-allocation of an existing level of risk between shareholders and customers.

1 Rather, given these higher current risks borne by the Company, investors would  
2 have required a higher equity return in the event the Company failed to secure  
3 approval of some form of power cost recovery mechanism in this case.

4 **Q. How do capital market concerns affect the cost of equity capital?**

5 A. As I discussed previously in Section II, equity investors respond to changing  
6 assessments of risk and financial prospects by changing the price they are willing  
7 to pay for a given security. When the risk perceptions increase or financial  
8 prospects decline, investors refuse to pay the previously existing market price for  
9 a company's securities, and market supply and demand forces then establish a new  
10 lower price. The lower market price typically translates into a higher cost of  
11 capital through a higher dividend yield requirement as well as the potential for  
12 increased capital gains if prospects improve. In addition to market losses for prior  
13 shareholders, the higher cost of capital is transmitted directly to the company by  
14 the need to issue more shares to raise any given amount of capital for future  
15 investment. The additional shares also impose additional future dividend  
16 requirements and reduce future earnings per share growth prospects.

17 **IV. Cost of Equity Capital for PacifiCorp**

18 **Q. What is the purpose of this section of your testimony?**

19 A. The purpose of this section is to present my quantitative studies of the cost of  
20 equity capital for PacifiCorp and to discuss the details and results of my analyses.

21 **Q. How are your studies organized?**

22 A. In the first part of my analysis, I apply alternative versions of the constant growth  
23 DCF and multistage DCF model to a comparable company group of electric

1 utilities. For inclusion in the group, each company is required to have at least a  
2 single-A bond rating, to have at least 70 percent of its revenues from regulated  
3 utility sales, to have consistent financial records not affected by recent mergers or  
4 restructuring, and to have a consistent dividend payment record with no recent  
5 dividend reductions or eliminations. Application of the minimum 70 percent  
6 regulated utility revenues filter results in a group *average* percentage of revenues  
7 from regulated utility sales of 86.0 percent, which helps to assure that non-  
8 regulated activities are not a significant influence for the group. The results of my  
9 DCF analyses are shown in Exhibit No.\_\_(SCH-4). In total, the DCF models  
10 produce an ROE range of 9.3 percent to 11.2 percent. As discussed previously,  
11 the 9.3 percent to 9.5 percent result from the traditional constant growth DCF  
12 model is not consistent with risk premium checks of reasonableness or other  
13 consensus economic forecasts for higher interest rates. Therefore, I do not  
14 include that result in my estimated DCF range. The appropriate range from the  
15 remaining DCF models is 10.7 percent to 11.2 percent.

16 In the second part of my analysis, I develop and review cost of capital  
17 estimates based on the risk premium methodology. I present my risk premium  
18 study in Exhibit No.\_\_(SCH-5). That analysis, based on allowed regulatory  
19 ROEs relative to contemporaneous utility debt costs, indicates that a cost of  
20 equity of 11.0 percent is appropriate. Other risk premium approaches indicate  
21 ROEs as high as 11.8 percent. Given current market and utility industry  
22 conditions, the risk premium approach adds useful perspective for judging  
23 investor requirements. Based on the DCF and risk premium results, and with

1 consideration for current market, industry, and company-specific factors  
2 appropriate for the present case, I estimate the cost of equity for PacifiCorp at  
3 11.125 %.

4 **A. Discounted Cash Flow Analysis**

5 **Q. What stock prices are used in your DCF analyses?**

6 A. My analysis is based on the average of high and low stock prices for each  
7 company for each of three recent months (January - March 2005). Although in  
8 theory either average or “spot” stock prices can be used in a DCF analysis, a  
9 reasonably current price consistent with present market conditions and with the  
10 other data employed in the analysis is most appropriate. Since the cost of equity  
11 is a current and forward-looking concept, the important issue is that the price  
12 should be representative of current market conditions and not unduly influenced  
13 by unusual or special circumstances.

14 **Q. Please summarize the results of your comparable company DCF analyses.**

15 A. I apply three versions of the DCF model to estimate ROE. The traditional  
16 Constant Growth version of the DCF model produces an ROE estimate of only  
17 9.3 percent to 9.5 percent. As shown in Exhibit No.\_\_\_\_(SCH-4), page 2, the  
18 average dividend yield in this model is 4.6 percent and the average growth rate is  
19 4.8 percent. The average growth rate is derived from traditional sources for  
20 estimating growth in the DCF model. Specifically, equal weight is given to  
21 (1) the sustainable growth “b times r” method, (2) Zacks' survey of individual  
22 company 5-year analysts' earnings estimates, (3) *Value Line's* projected 3-to-5  
23 year earnings growth rate, and (4) long-term growth in nominal Gross Domestic

1 Product (GDP). The “b times r” method and the analyst and *Value Line* earnings  
2 projections are significantly and negatively influenced by the uncertainties,  
3 discussed previously, that are currently affecting the industry. The “b times r,”  
4 *Zacks*, and *Value Line* growth rates average only about 4.14 percent, which is  
5 only about two-thirds of the 6.6 percent growth rate for long-term GDP. The 9.3  
6 percent to 9.5 percent ROE estimate from the traditional constant growth DCF  
7 approach is not consistent with consensus economic projections for higher interest  
8 rates and is 1.7 percent to 2.3 percentage points below current risk premium  
9 checks of reasonableness. For these reasons, I do not include the traditional  
10 constant growth DCF result in my recommended ROE range.

11 The non-constant growth Two-Stage DCF model indicates an ROE of 10.7  
12 percent to 10.8 percent. For stage one of this model (years 1 through 4), the  
13 growth rate is based on *Value Line*'s projected dividends. The average growth  
14 rate for stage 1 of this model is only 3.28 percent. The growth rate for stage 2 is  
15 the nominal growth rate in GDP noted above. In combination with the 4.6 percent  
16 average dividend yield, the 10.7 percent to 10.8 percent ROE range from this  
17 model implies an overall growth expectation of 6.1 percent to 6.2 percent. This  
18 implied growth rate is based on the traditional yield plus growth DCF format  
19 (10.7 percent ROE = 4.6 percent yield + 6.1 percent growth; 10.8 percent ROE =  
20 4.6 percent yield + 6.2 percent growth).

21 My third DCF model is based on the constant growth approach, but with  
22 the growth rate strictly proxied by the 6.6 percent long-term GDP growth rate.  
23 That model indicates an ROE of 11.2 percent. As discussed previously, based on

1 expected further increases in market interest rates and other capital market costs,  
2 it is my judgment that the fair cost of equity range should be based on the Two-  
3 Stage growth DCF model and the Constant Growth model with long-term GDP  
4 used as a proxy for long-term investor growth rate expectations. Based on these  
5 two versions of the DCF model, the ROE range is 10.7 percent to 11.2 percent.

6 **B. Risk Premium Analysis**

7 **Q. How is your risk premium study structured?**

8 A. In my risk premium analysis, I compare authorized electric utility ROEs to  
9 contemporaneous long-term interest rates on utility bonds. The equity risk  
10 premium then is measured by the difference between the average authorized ROE  
11 and the average debt cost for each year. This calculation for the period, 1980 -  
12 2004, is presented in Exhibit No.\_\_(SCH-5). The data show that risk premiums  
13 are smaller when interest rates are high and larger when interest rates are low.  
14 For example, in the early 1980s when utility interest rates exceeded fifteen  
15 percent, allowed equity risk premiums were generally less than two percent. In  
16 more recent years, with lower interest rates, allowed regulatory risk premiums  
17 have generally been in the three- to four-percent range.

18 The inverse relationship between risk premiums and interest rate levels is  
19 well documented in numerous, well-respected academic studies. (*See, for*  
20 *example, Robert S. Harris and Felicia C. Marston, "Estimating Shareholder Risk*  
21 *Premia Using Analysts' Growth Forecasts," Financial Management, Summer*  
22 *1992.*)

1           These studies typically use regression analysis or other statistical methods  
2 to predict or measure the risk premium relationship under varying interest rate  
3 conditions. In Exhibit No. \_\_\_\_ (SCH-5), page 2, I present a regression analysis of  
4 the allowed annual equity risk premiums relative to interest rate levels. The  
5 regression coefficient of minus 42.18 percent confirms the inverse relationship  
6 between risk premiums and interest rates and indicates that risk premiums expand  
7 and contract by about fifty-eight percent of the change in interest rates. This  
8 means that when interest rates rise by one percentage point, the cost of equity  
9 increases by only 0.58 of a percentage point, because the risk premium declines  
10 by about 0.42 percentage points. Similarly, when interest rates decline by one  
11 percentage point, the cost of equity declines by only 0.58 of a percentage point. I  
12 use the minus 42.18 percent interest rate change coefficient in conjunction with  
13 current interest rates to establish the appropriate current equity risk premium.  
14 This calculation is shown in the lower portion of page 1 of Exhibit No. \_\_\_\_ (SCH-  
15 5). When the resulting risk premium of 4.25 percent is added to the projected  
16 single-A utility debt cost of 6.7 percent, the indicated ROE is 11.0 percent (4.25%  
17 + 6.7% = 10.95%).

18 **Q. How do the results of your risk premium studies compare to levels found in**  
19 **other risk premium studies?**

20 A. My risk premium estimate is lower than those often found in other risk premium  
21 studies. From the most widely followed data published by Ibbotson Associates  
22 (Ibbotson Associates, *Stocks, Bonds, Bills and Inflation 2004 Yearbook*), for the  
23 period 1926-2003, the indicated arithmetic mean risk premium for common

1 stocks versus long-term corporate bonds is 6.2 percent. Under the more  
2 conservative assumption of geometric mean compounding, the Ibbotson risk  
3 premium is 4.5 percent. Ibbotson argues extensively for the arithmetic mean  
4 approach as the appropriate basis for estimating the cost of equity. Even with the  
5 more conservative geometric mean risk premium, Ibbotson's data indicate a  
6 single-A cost of equity of 11.2 percent (6.7 percent debt cost + 4.5 percent risk  
7 premium = 11.2 percent).

8 The Harris and Marston (H&M) study noted above also provides specific  
9 equity risk premium estimates. Using analysts' growth estimates to estimate  
10 equity returns, H&M found equity risk premiums of 6.47 percent relative to U.S.  
11 Government bonds and 5.13 percent relative to yields on corporate debt. H&M's  
12 equity risk premium relative to corporate debt indicates a current single-A cost of  
13 equity of 11.8 percent (6.7 percent debt cost + 5.13 percent risk premium = 11.83  
14 percent).

15 **Q. Please summarize the results of your cost of equity analysis.**

16 A. The following table summarizes my results:

Summary of Cost of Equity Estimates	
<u>DCF Analysis</u>	<u>Indicated Cost</u>
Constant Growth Model (traditional growth)	9.3% - 9.5%
Constant Growth Model (GDP growth)	11.2%
Two-Stage Growth Model	10.7% - 10.8%
Estimated DCF Model Range	<u>10.7% - 11.2%</u>
Risk Premium Analysis	
Utility Debt + Risk Premium	
Risk Premium Analysis (6.7% + 4.25%)	11.0%
Ibbotson Risk Premium Analysis	
Risk Premium (6.7% + 4.5%)	11.2%
Harris-Marston Risk Premium	
Risk Premium (6.7% + 5.13%)	11.8%
PacifiCorp Fair Cost of Equity Capital	<u>11.125%</u>

20 **Q. How should these results be interpreted to determine the fair cost of equity**  
 21 **for PacifiCorp?**

22 A. At 11.125 %, my recommended ROE is near the middle of the appropriate DCF  
 23 model range and the lower end of the risk premium range. This ROE level  
 24 represents a reasonable balance between consensus economic forecasts for  
 25 significantly higher interest rates during the rate effective period and the lower  
 26 ROEs that can be obtained from traditional DCF methods based on recent  
 27 historically low dividend yields and traditional DCF growth estimate  
 28 methodologies. Under present market conditions, I believe that this is the most  
 29 appropriate approach for estimating the fair cost of equity capital.

30 **Q. Does this conclude your direct testimony?**

31 A. Yes.
