And Termination)**

DOCKET NO. UT-023003

REPLY TESTIMONY OF DR. ROBERT A. MERCER

on behalf of

AT&T COMMUNICATIONS OF THE PACIFIC NORTHWEST, INC.

May 12, 2004

1 **I. IDENTIFICATION OF WITNESS**

2 **Q. PLEASE STATE YOUR NAME AND BUSINESS ADDRESS.**

3 A. My name is Robert A. Mercer. I am the Principal of BroadView Telecommunications,
4 LLC (“BVT”), a consulting firm specializing in analyses of the telecommunications
5 infrastructure. The address of the firm is 5201 Holmes Place, Boulder, Colorado, 80303.

6 **Q. ARE YOU THE SAME DR. ROBERT A. MERCER THAT FILED DIRECT
7 TESTIMONY ON BEHALF OF AT&T IN THIS PROCEEDING?**

8 A. Yes, I am. My resume was included as Exhibit RAM-1 to that Direct Testimony.

9 **Q. WHAT IS THE PURPOSE OF THIS SURREBUTTAL TESTIMONY?**

10 I will respond to assertions made in the reply testimonies of Verizon witnesses Dr.
11 Timothy Tardiff, Christian Dippon, and Francis J. Murphy. I will focus on their
12 numerous mischaracterizations of the attributes and operation of the HAI Model, Release
13 5.3 (“HM 5.3). Other AT&T witnesses will address claims made by the Verizon
14 witnesses pertaining to their detailed areas of expertise.

15 **II. RESPONSE TO THE TESTIMONY OF TIMOTHY J. TARDIFF**

16 **Q. PLEASE SUMMARIZE THE NATURE OF DR. TARDIFF’S TESTIMONY
17 ABOUT HM 5.3 AND ITS INPUTS**

18 A. The gist of Dr. Tardiff’s testimony is his claim that the HM5.3 Model produces too little
19 investment in network facilities and too few costs associated with that investment.
20 Furthermore, he asserts, the Model has not been subject to reasonable validation tests.
21 Dr. Tardiff claims that there are a number of reasons why the Model fails to produce
22 sufficient investments and costs. These reasons fall into three categories, as alleged by

1 Dr Tardiff: 1) broad theoretical issues, including the Model’s alleged failure to
2 appropriately incorporate TELRIC principles and its unrealistic sizing of network
3 facilities to meet current demand with insufficient excess capacity for growth; 2) issues
4 pertaining to the Model’s inputs, including the purported use of unsubstantiated,
5 subjective judgments for various outside plant inputs, and an unrealistically low cost of
6 capital and long depreciation lives; and 3) allegedly mistaken assumptions and errors
7 pertaining to various Model details.

8 **Q. PLEASE SUMMARIZE YOUR OVERALL RESPONSE TO DR. TARDIFF’S**
9 **CRITICISMS OF HM 5.3.**

10 .A. Five overarching comments are in order about these criticisms. First, for the most part,
11 they are stale and outdated. Dr. Tardiff has been leveling many of these criticisms for
12 years, particularly those pertaining to non-compliance with TELRIC principles and the
13 blatantly false implication that the Model only installs “the equipment it will need at a
14 single point in time.” (Tardiff, p. 11) Such arguments have been frequently repudiated,
15 as they should have been because they are false.

16 Second, a large majority of his criticisms address Model inputs. Should this Commission
17 believe that any of his criticisms about input values – component prices, cost of capital,
18 depreciation lives, etc. – are valid, they can readily change the inputs in the Model. The
19 Model has been parameterized with more than 2,100 inputs to allow just this kind of
20 flexibility. Using a “wrong” input value does not invalidate the HM 5.3 platform.

21 Third, Dr. Tardiff’s criticisms of HM 5.3, particularly its inputs, are never accompanied
22 by constructive alternatives, or even meaningful evidence that substantiates his claims.

1 For instance, while criticizing the prices of outside plant components used in the Model
2 (and, for that matter, outside plant design practices assumed by the Model) because, he
3 alleges, they are based on subjective, unsubstantiated opinions, he neither offers concrete
4 evidence that the inputs and practices are wrong, nor does he offer alternative prices and
5 practices he believes are more reliable, accompanied by supporting evidence. He simply
6 does not like the findings of experts with decades of experience reviewing available data
7 to arrive at reasoned judgments about inputs, and specifying the design practices HM 5.3
8 should follow. Similarly, while he (wrongly) criticizes the Model for having insufficient
9 excess capacity, he offers no constructive comments as to how much extra capacity
10 should be included in the Model.

11 Fourth, his complaints, like those of other Verizon witnesses, are never accompanied by a
12 quantitative assessment of the impact of the alleged mistakes on the Model's results. It is
13 hardly worth the Commission's attention to focus on criticisms which, even if valid,
14 would have a minor effect on the results.

15 Finally, with two exceptions, Dr. Tardiff's claims about specific aspects of the Model's
16 assumptions and calculations are without merit, as are the claims by other witnesses to
17 which Dr. Tardiff refers. The two exceptions are discussed at the appropriate point in
18 this testimony. One has to do with Dr. Tardiff's attempt to use a special Model feature
19 that we had not intended to implement in Washington and that will not work as the Model
20 is currently configured. The other concerns a potential modification in the way the
21 Model determines whether the loop distances involved in a particular cluster require the
22 use of fiber feeder and/or subdividing the cluster into smaller serving areas.

1 **Q. ARE DR. TARDIFF’S CLAIMS ABOUT THE LACK OF VALIDATION OF THE**
2 **HM 5.3 MODEL LEGITIMATE?**

3 A. No. These claims are based on two arguments put forth by Dr. Tardiff. First, when one
4 compares the investment and cost results produced by HM 5.3, they fall short of the
5 current investments and costs reported by Verizon in its ARMIS data. Second, he claims,
6 AT&T/MCI have not tested, let alone verified, whether HM 5.3 produces valid and
7 accurate estimates of network investments. The first of these claims is irrelevant; the
8 second is wrong.

9 **Q. WHY IS THE COMPARISON OF THE INVESTMENTS AND COSTS**
10 **PRODUCED BY HM 5.3 WITH VERIZON’S ARMIS DATA IRRELEVANT?**

11 A. It is irrelevant because from the time the FCC adopted its TELRIC principles in the First
12 Report and Order on Local Competition, it specifically excluded embedded costs from its
13 definition of TELRIC. The U.S. Supreme Court also weighed in on this matter,
14 dismissing the ILECs’ comparison of model results with embedded data in harsh terms.

15 As for state proceedings, in the most recent findings in a UNE proceeding, the Proposed
16 Decision by the Administrative Judge in the SBC-California UNE case (“SBC-CA
17 Proposed Decision),” flatly rejects such a comparison in the following terms

18 We do not agree with SBC-CA that HM 5.3 is automatically flawed
19 because its proposed costs are lower than SBC-CA actual costs. SBC-CA
20 makes generic statements that the characteristics of its current network
21 best reflect an efficient forward-looking network because SBC-CA has
22 years of experience running a network and has been operating under
23 incentive regulation designed to make its network competitive. SBC-CA
24 actual costs may not be forward-looking, may be skewed by unusual one-
25 time expenses from that year, or may simply reflect the cost of running a
26 network based on embedded choices that a new carrier would not make.
27 In many ways, we consider SBC-CA’s comparisons of model results to its

1 actual network experience irrelevant because its actual costs may not be
2 forward-looking. Further, we find these comparisons less useful because
3 they are often made at a very aggregate level and do not allow us to
4 compare discrete modeling results in an “apples to apples” fashion.

5 SBC-CA’s attempt to argue that HM 5.3 results are unrealistic when
6 compared to SBC-CA’s current operations appears to echo the
7 unsuccessful arguments that ILECs presented to the U.S. Supreme Court.
8 The Supreme Court recognized that “the problem with a method that relies
9 in any part on historical cost, the cost incumbents say they actually incur,
10 is that it will pass on to lessees the difference between most-efficient cost
11 and embedded cost.” (Verizon, 122 S. Ct. at 1673.) The court flatly
12 rejected the idea of basing UNE costs on costs from SBC-CA’s network
13 today. (Proposed Decision, pp. 67-68)

14 Above and beyond these findings that ARMIS provides investments and costs associated
15 with an embedded network, there are other reasons why HM 5.3 results should not be
16 compared with ARMIS data. Prominent among these is the fact that ARMIS data contain
17 a number of investments and costs associated with activities that are excluded from UNE
18 rates. These include, for instance, marketing and most product management expenses.
19 HM 5.3 appropriately assigns significant fractions of many categories of general support
20 and overhead investment and expenses, such as those associated with buildings, land,
21 furniture, and general purpose computers to such activities, and excludes them from the
22 Model’s calculations. In addition, ARMIS data may include investments and costs
23 associated with elements for which UNEs are not being developed (such as fiber-based
24 services other than DS-3), may reflect the provision of excess amounts of capacity or
25 capacity for as-yet-not-offered services, and the like.

26 In light of all these considerations and past findings, Dr. Tardiff is beating a dead horse
27 by continuing to attempt to indict HM 5.3 on the basis that it does not produce results
28 close to those reported in ARMIS data.

1 **Q. WHAT ABOUT DR. TARDIFF’S CLAIMS THAT AT&T HAS NOT VERIFIED,**
2 **LET ALONE TESTED, THE INVESTMENTS IT PRODUCES?**

3 A. Given that HM 5.3 models a forward-looking network, not the incumbent’s embedded
4 network, any comparisons of the Model’s investment and cost results with incumbents’
5 results are highly suspect. Furthermore, the absolute level of investment, and thus of
6 expenses, produced by the Model are critically dependent on the input values used in the
7 Model. I have already commented that the merits of the Model’s platform – that is, the
8 assumptions, algorithms, and calculations of the Model -- are a separate issue than the
9 values used for the Model’s inputs. Dr. Tardiff blurs this critical distinction.

10 There is a comparison the Model’s sponsors have consistently tried to make that is
11 independent of the Model’s inputs for investment and cost. It is the total amount of
12 outside plant route miles produced by the Model compared to the incumbent’s route
13 miles. While Dr. Tardiff apparently disagrees,¹ I believe route miles to be a more
14 meaningful comparison than average loop length, because the latter is strongly influenced
15 by the particular configuration of serving areas in a wire center and by the placement of
16 the serving area interface (SAI) within a serving area. As AT&T witness Mr. Fassett
17 testifies, distribution areas may be established and structured differently than those in the
18 existing network (Fassett Reply Testimony, p. 10). Average loop length is likely to
19 change, perhaps significantly, as a result of the restructuring of distribution areas. On the
20 other hand, while it may be possible to lay out the loop plant in a way that somewhat
21 reduces the total route miles required to connect all customers to each other and the wire
22 center that serves them, customers are where they are, and mathematics dictates that a

1 certain amount of cable is required to reach them no matter how much restructuring is
2 done.

3 When we have received the necessary data from the incumbents, we have generally found
4 that HM 5.3 produces more route miles than currently exist in the incumbent's network.
5 This is not surprising – the Model is conservative in a number of key respects, an
6 important one being that it assumes right-angle, rather than straight line, routing between
7 two points. In mathematical terms, this means one follows the two legs of a right triangle
8 whose acute vertices are the two points in question, rather than following the hypotenuse
9 of the triangle. It is a straightforward mathematical exercise to show that assuming right
10 angle routing adds an average of 27% to the straight-line route distance.

11 Unfortunately, while Verizon has average loop length data by wire center, it does not to
12 my knowledge have the total route mile information. On the other hand, Verizon's
13 VzLoop model provides route mile information. In some ways, for the sake of selecting
14 a cost model, this is even more valuable than knowing the route miles in the existing
15 network, because it allows the direct comparison of the two models' results. Mr. Dippon
16 has presented the following comparison of the total outside plant route miles between
17 HM 5.3 and the Verizon VzLoop model:

18 HM 5.3 models a total loop route distance of 95,642,749 feet, or 18,114
19 miles. VzLoop, on the other hand, models a total loop route distance of
20 79,486,330 feet, or 15,054 miles—17 percent less than HM 5.3. Similarly,
21 HM 5.3 models 80,659,622 feet of distribution cable, while VzLoop
22 models 57,086,648 feet. (Dippon Testimony, p. 63)

(continued)

¹ Tardiff, p. 96.

1 Thus, HM 5.3 is producing a conservatively higher estimate of route miles than is the
2 Verizon cost model. Given this comparison, it strikes me as ironic that Dr. Tardiff would
3 nevertheless imply HM 5.3 is defective because

4 For example, the cost model must produce feeder and distribution routes
5 of sufficient lengths, (Tardiff testimony, at p. 3)

6 and that the Model

7 only serves to produce uneconomically low cost estimates. In particular,
8 the hypothetical routes modeled and facilities deployed by HM 5.3 do not
9 take into account real-world obstacles such as rivers and roads -- an
10 erroneous modeling technique that unjustifiably decreases costs. (Tardiff,
11 p. 9, emphasis added)

12 **Q. PLEASE COMMENT ON DR. TARDIFF’S ASSERTION THAT HM 5.3 FAILS**
13 **TO INCORPORATE APPROPRIATE TELRIC PRINCIPLES.**

14 A. Similarly to his comparison of model investments and costs with ARMIS data, Dr.
15 Tardiff has made this claim in a number of state proceedings. The claim has not fared
16 well in the outcomes of those proceedings. The SBC-CA Proposed Decision found

17 SBC-CA’s criticisms of HM 5.3 principally highlight questionable inputs
18 that [Joint Applicants] have used in HM 5.3, but we do not agree that HM
19 5.3 violates TELRIC requirements overall. SBC-CA takes issue with how
20 HM 5.3 applies TELRIC to build a network instantaneously to meet
21 current demand. While we agree that it may be unrealistic to assume a
22 network can be constructed overnight, we find that HM 5.3 for the most
23 part follows well-established TELRIC guidance and SBC-CA’s criticisms
24 center largely around quarrels with the inputs that are used in the model.
25 (Proposed Decision, p. 64)

26 Given that Dr. Tardiff’s claims have been found to be specious, and that my
27 Supplemental Direct Testimony dealt at some length with HM 5.3’s consistency
28 with the FCC’s TELRIC principles, I will not further discuss his claims to
29 the contrary.

1 Q. DR. TARDIFF CLAIMS HM 5.3 DOES NOT PROVIDE SUFFICIENT
2 CAPACITY FOR GROWTH. IS THIS A VALID CRITICISM OF THE MODEL?

3 A. No, it is not. As with his discussion of ARMIS comparisons and compliance with
4 TELRIC (of which this discussion about capacity is an adjunct), this is a careworn
5 argument that is simply inconsistent with the facts about HM 5.3. According to Dr.
6 Tardiff,

7 HM 5.3 specifically excludes, by design, the costs incurred in operating a
8 dynamic network (i.e., one with sufficient capacity) on a going-forward
9 basis. A network with insufficient capacity to accommodate churn,
10 irregularly distributed demand, fluctuations in demand over time, and
11 overall growth in demand, cannot serve a carrier's customers
12 without an unacceptable risk of service disruption or a high probability
13 that customer demand for service would go unsatisfied. A network cannot
14 be said to "serve" existing demand if it is not flexible enough to
15 accommodate changes and rearrangements in that demand. . . .

16
17 In this environment, it is not efficient for a telecommunications carrier to
18 install only the equipment it will need at a single point in time. Rather, an
19 efficient carrier will install plant that includes enough capacity so that the
20 utilization of that capacity (e.g., "fill factors") are adequate to: (1)
21 accommodate movement of existing customers and their services, (2) meet
22 short-run demand growth (e.g., two to three years for new switches), and
23 (3) implement growth jobs and upgrades over the life of the plant.
24 (Tardiff, pp. 10-11, emphasis added)

25 One of the problems with HM 5.3's modeling approach is its removal of a
26 substantial amount of the current, and very real, costs needed to
27 accommodate growth and respond to changes in demand. HM 5.3
28 implicitly assumes that an ILEC would instantly size its entire outside
29 plant network based on the amount and location of current demand, and
30 thereby realize unrealistic economies that can only be obtained when total
31 demand is served by ideally-sized facilities purchased at maximum
32 volume discounts. (Tardiff, p. 12, emphasis added)

33 There are numerous problems with Dr. Tardiff's argument. First and foremost, he and I
34 disagree about how much excess capacity for growth a properly-crafted model like HM
35 5.3 should provide – and, I would add, HM 5.3 does provide sufficient excess capacity.

1 For instance, as the Model output demonstrates, the overall distribution fill attained by
2 the Model is 48.5% percent.² Given the way the Model calculates costs, this means that
3 each working line pays for more than two lines over the lifetime of the distribution cable,
4 with no later relief as customers purchase additional lines, or new businesses or
5 households are added to the area where a cable is currently installed. HM 5.3 thus
6 provides a substantial amount of excess capacity in distribution cable to accommodate
7 growth, churn, and customer rearrangements, and it is misleading for Dr. Tardiff not to
8 acknowledge that fact . As for the general issue of providing extra capacity, HM 5.3
9 calculates costs taking into account utilization factors not only for distribution cable, but
10 for feeder and interoffice cable, local and tandem switching, loop and interoffice digital
11 circuit equipment, and signaling elements – in short, every component of the network
12 where extra capacity may be required for the reasons Dr. Tardiff cites. While it is true
13 the fill factors in the Model are generally set higher for components other than
14 distribution cable, that is done in recognition that adding extra capacity in other parts of
15 the network – switched lines, plug-in cards in various kinds of circuit equipment, etc. – is
16 a simpler, faster process than placing new distribution cables.

17 Second, while Dr. Tardiff still complains that the Model is sized only to meet current
18 demand, which is manifestly false, he also makes the less extreme statement that HM 5.3
19 is defective due to its “modeling of lower amounts of capacity (or higher fill factors) than
20 Verizon NW maintains in its network.” (Tardiff, p. 9). But matching the fill factors the
21 incumbent maintains in its current network is *a priori* inconsistent with the TELRIC
22 requirement to exclude embedded costs. According to the SBC-CA Proposed Decision:

² Density Zone Expense Module output, “Cost Detail” worksheet, Cell K57.

1 There are several reasons why we find that SBC-CA has not met its
2 burden of proving that its embedded fill level is a reasonable proxy for
3 forward-looking utilization. First, when setting the copper distribution fill
4 factor in the prior OANAD proceeding, the Commission adopted a level 5
5 percent higher than SBC-CA's embedded fill level. (D.96-08-021,
6 *mimeo.*, p. 30.) SBC-CA has not provided any new rationale for using its
7 actual fill levels now. SBC-CA merely proposes that its current fill rates
8 are forward-looking on the reasoning that its current achieved fill is
9 expected to remain at the same level in the future and because its fill rates
10 have remained unchanged for some time. SBC-CA has not provided an
11 analysis to show that the current fill level may be either too low or too
12 high. The fact that SBC-CA has maintained the same fill level over time
13 does not prove that level is efficient. While SBC-CA reiterates that fill
14 levels have remained constant over time, this could merely be because
15 SBC-CA works to ensure the fill remain constant. It does not mean that
16 this is optimum.

17 Second, the FCC has not looked favorably on excessive levels of spare
18 capacity or sizing a forward-looking network to serve ultimate demand.
19 SBC-CA's fill level leaves approximately two-thirds of its network
20 unused, and the FCC has criticized this much spare as excessive. Further,
21 SBC-CA sizes its network based on projections of usage exceeding two
22 lines per household without reconciling this standard to current growth
23 estimates or its own temporary guidelines calling for less than two lines
24 per house. SBC-CA interprets the FCC as supporting the use of embedded
25 fills as forward-looking based on an FCC statement that fill factors must
26 be based on a reasonable projection of actual total usage. We find it more
27 reasonable to read this FCC passage as supporting the concept that a
28 forward-looking fill factor should reasonably project actual usage, not that
29 embedded fill levels are automatically forward-looking.

30 Third, we are not persuaded that a fill level of 51.6% will cause dramatic
31 service delays or installation cost increases, as suggested by SBC-CA. In
32 Section VI.E.8 below, we discuss why SBC-CA's correlation of fill
33 factors and maintenance expenses is not persuasive. Moreover, a fill level
34 of 51.6%, only 10 percent above the fill level proposed by SBC-CA, is
35 premised on the installation of 1.5 to 2 lines per household and leaves 48%
36 spare capacity. It is reasonable to conclude that this level of spare can
37 accommodate customer churn, maintenance, and growth without the need
38 for service interruptions or the installation of additional lines. (SBC-CA
39 Proposed Decision, pp. 167-168, emphasis added)

40 The final problem with Dr. Tardiff's arguments about fill factors is that, once again, he
41 has blurred the distinction between the model platform and its inputs. Even if Verizon
42 were to prevail in its argument that fills should be set to the level of its embedded

1 network, as Dr. Tardiff appears to propose, the fill factors for all categories of equipment
2 are user-adjustable inputs in HM 5.3.

3 **Q. DR. TARDIFF OFFERS A SET OF DETAILED CRITICISMS OF THE**
4 **MODEL'S OPERATION. WHAT IS YOUR REACTION TO THESE**
5 **CRITICISMS?**

6 A. In general, they are assertions without proof or even substantive arguments underlying
7 them, they are often misleading and/or erroneous, they ignore serious problems with
8 Verizon's alternative approach, notably the extensive use of information taken from
9 Verizon's embedded network, and they are presented with no quantitative assessment of
10 the impact they have on the Model's results. I will not deal with each and every such
11 criticism, but will focus on those that may raise concerns with the Commission because
12 they may appear to be legitimate and potentially of significant impact on the results. Any
13 I do not discuss are, in my opinion, obviously wrong or of little potential impact.

14 **Q. DO YOU AGREE WITH DR. TARDIFF THAT MORE THAN ROUTE**
15 **DISTANCE AFFECTS THE AMOUNT OF INVESTMENT REQUIRED IN**
16 **OUTSIDE PLANT FACILITIES (TARDIFF, P. 24)?**

17 A. Yes, of course I do, and I have never made a representation to the contrary. For instance,
18 outside plant investment along a given route is affected by cable size and type (copper
19 wire gauge, copper versus feeder), type of structure (aerial, buried, and underground), the
20 amount of structure sharing with other utilities and between different components of the
21 Verizon network (e.g., sharing of structures by distribution, feeder, and distribution
22 routes), and HM 5.3 takes all such factors into account. To treat such factors
23 appropriately, a team of outside plant experts advised the HAI Model developers as to

1 how the Model should design outside plant. That advice included the identification of
2 design parameters that should be available to the Model’s users as inputs so they could be
3 varied as necessary in a particular jurisdiction or for the purpose of testing the sensitivity
4 of the Model. In each such jurisdiction, one or more outside plant experts typically
5 advise the Model’s sponsors as to the input values that should be used. Mr. Dean Fassett
6 has performed that role in this proceeding.

7 The reason I put a lot of emphasis on route distance (or average loop length, if route
8 distance information is not available) is because Dr. Tardiff and other ILEC witnesses in
9 various jurisdictions have repeatedly claimed that the Model produces an insufficient
10 amount of cable to reach all the customer locations. These claims rest on unsubstantiated
11 or misleading statements, such as that the Model ignores real-world constraints (Tardiff,
12 pp. 22-23) or doesn’t use the customer location information determined by TNS (Tardiff,
13 Footnote 35, p. 22).

14 **Q. DR. TARDIFF CLAIMS THE VERIZON MODEL IS SUPERIOR TO HM 5.3**
15 **BECAUSE IT TAKES INTO ACCOUNT THE ACTUAL ROAD LOCATIONS**
16 **AND RIGHTS OF WAY WHEN IT ROUTES CABLES, WHEREAS HM 5.3**
17 **DOES NOT (TARDIFF, P. 23, LINES 3-10). IS THIS AN ACCURATE**
18 **STATEMENT?**

19 A. No. Verizon presenters in a recent California workshop admitted that VzLoop links
20 terminal locations using straight-line cable segments, not segments that follow the actual
21 roads and other rights-of-way. In that sense, the Verizon model will actually tend to
22 produce fewer route miles than does HM 5.3, because VzLoop makes a highly unrealistic
23 straight-line routing assumption whereas HM 5.3 uses right angle routing to account for

1 geographic and other routing constraints. Thus it is not surprising Mr. Dippon finds HM
2 5.3 actually produces more, not less, route miles than does VzLoop. Dr. Tardiff has thus
3 turned the actual situation upside down -- it is HM 5.3 that accounts for routing
4 constraints, whereas VzLoop does not.

5 **Q. DR. TARDIFF CLAIMS THAT THERE ARE MANY DESIGN ERRORS DUE TO**
6 **THE OVERSIZED CLUSTERS USED IN THE MODEL, AND THESE CAN'T BE**
7 **FIXED BECAUSE THE CLUSTERS ARE DEFINED IN A PRE-PROCESSING**
8 **STEP BEFORE THE MODEL RUNS. IS HE CORRECT?**

9 A. No, and this claim single-handedly demonstrates several of the overarching flaws in Dr.
10 Tardiff's criticisms. First, he provides no evidence the clusters are oversized, nor even
11 why he believes that to be the case. Clusters are allowed to be as large as they are in HM
12 5.3 because the outside plant experts advising the HM 5.3 developers said that the
13 clusters reasonably could be that large to take advantage of the capacity available in
14 controlled environment vaults and associated digital loop carrier equipment. Second, Dr.
15 Tardiff presents no alternative maximum size cluster that should be utilized instead.³
16 Third, he has not quantified what effect if any changing the maximum cluster size would
17 have on the results. And, finally, he ignores the fact that one of his colleagues, Mr.
18 Dippon, did change the maximum cluster size criterion and reran the Model with new
19 clusters. The result of that analysis was that the cost results changed very little. Mr.
20 Dippon found that result unreasonable, but Mr. Donovan and I have both explained on
21 prior occasions that the result is what one would expect.

1 **Q. DR. TARDIFF CLAIMS IT IS NOT REASONABLE FOR A REDUCTION IN**
2 **INVESTMENT TO CAUSE A CORRESPONDING REDUCTION IN EXPENSES**
3 **CALCULATED BY THE MODEL (TARDIFF, P. 50, AND PP. 90-92). DO YOU**
4 **HAVE ANY COMMENTS ON HIS DISCUSSIONS OF THIS SUBJECT?**

5 A. In these passages, Dr. Tardiff is complaining about the fact that the operating expenses
6 associated with a particular plant category are calculated as a ratio of expense to
7 investment (“E/I”) for that category times the forward-looking investment estimated by
8 the Model, so when the forward-looking investment is less, the direct expenses will be
9 less as well. Many cost models calculate plant-specific operating expenses in this
10 fashion, including the FCC Synthesis Model, the model presented by SBC-California in
11 the UNE proceeding in that state, HM 5.3, and Verizon’s cost models in this proceeding.
12 There is good reason for calculating expenses in this fashion. In California, AT&T and
13 MCI witnesses Tom Brand and Art Menko demonstrated the strong correlation between
14 plant expenses and investments that justifies this treatment.

15 There are two reasons why the investment in a given plant category produced by HM 5.3
16 might be lower than the corresponding amount in Verizon’s embedded data, causing the
17 Model to produce less direct expenses associated with that plant category through the
18 application of an E/I ratio. One is that the price per unit of material has dropped. The
19 other is that the Model produces a lower quantity of plant. Dr. Tardiff addresses the first
20 reason. His point that changing the unit price of an item of plant due to vendor discounts

(continued)

³ Dr. Tardiff talks several times about clusters sized for 200-600 lines, but he attributes that size to an earlier statement by AT&T witness John Donovan, and he also admits the average cluster size in VzLoop is considerably larger than 600 lines.

1 (or any other reason) is correct. But it is irrelevant to the extent the Model correctly
2 represents the price Verizon pays for a unit of equipment, which is what the Model’s
3 inputs do.⁴

4 This leaves the other consideration – that the forward-looking Model calculates a lesser
5 quantity of material investment than Verizon has in its embedded network, and therefore
6 the application of an E/I ratio to that lower level of investment produces lower expenses.
7 This is an entirely appropriate result in a forward-looking cost model. The fact that
8 Verizon has eliminated this effect, by applying a correction factor to the E/I ratio so as to
9 maintain the current level of expenses (Tardiff, p. 91, Footnote 132) is an indictment of
10 the Verizon models, not of HM 5.3.

11 **Q. DR. TARDIFF CLAIMS THAT THE FACT HM 5.3 PRODUCES LOOP COSTS**
12 **LESS THAN THE VZCOST MODEL IS UNREASONABLE BECAUSE OF THE**
13 **“EXPECTATION OF MCI’S COUNSEL, THE UNITED STATES SUPREME**
14 **COURT, AND THE CLECS THEMSELVES THAT LOOP FACILITIES DO NOT**
15 **EXHIBIT THE POTENTIAL FOR RAPID COST REDUCTION LIKE OTHER**
16 **NETWORK COMPONENTS” (TARDIFF, P. 52). IS THIS A VALID POINT?**

17 A. No, it is absurd. The fact that HM 5.3 produces a cost lower than Verizon’s embedded
18 costs, or those estimated by Verizon’s cost model, says nothing whatsoever about the
19 trend in loop prices. For instance, HM 5.3 does not assume future network component
20 prices will be lower than they are today, nor that the operations cost per unit of

⁴ One might argue that the embedded investments represent historical purchases, whereas the Model utilizes forward-looking investments based on today’s prices. Recognizing this, the FCC took the current-to-book price ratios into account in calculating the E/I ratios that have been utilized in the Washington runs of HM 5.3.

1 investment (i.e., the E/I ratios) should be less than the FCC found appropriate based on
2 the analysis of the incumbents' existing expenses. The fact that HM 5.3 produces lower
3 costs than Verizon's booked costs says only that Verizon's embedded costs are not a
4 good indication of its true costs to provide UNEs, for the reasons outlined earlier. As for
5 the comparison of HM 5.3 and VzCost results, the lesson to be learned is that one has to
6 consider two competing models on the relative merits of their platforms and inputs.

7 **Q. SIMILARLY, DR. TARDIFF CLAIMS THAT BECAUSE LATER VERSIONS OF**
8 **THE HAI MODEL PRODUCE LOWER LOOP COSTS THAN DO EARLIER**
9 **VERSIONS OF THE MODEL, THIS MEANS THE MODEL IS ASSUMING**
10 **TECHNOLOGICAL DEVELOPMENTS THAT WILL LOWER LOOP COSTS**
11 **(TARDIFF, PP. 55-56). IS THIS A CORRECT REPRESENTATION OF THE**
12 **MODEL'S ASSUMPTIONS?**

13 A. No. The differences demonstrate only that the Model itself has advanced, both in the
14 sophistication of its modeling techniques and in its subject matter experts' knowledge of
15 the proper input values the Model should utilize. The Model assumes the same network
16 configurations and loop technologies that it has assumed from the earlier versions. But it
17 is much more sophisticated in its approach.

18 For example, non-POTs loops, particularly DS-3 and other broadband loops, share
19 outside plant structures and can utilize pairs/strands in the same cables as are used for
20 POTs. This produces economies of scope in the provision of multiple loop types. Thus,
21 the FCC's guidelines for UNE models were that all loop demand should be taken into
22 account (subject, of course, to having the modeling technology that allows this to be
23 done). Earlier versions of the HAI Model were unable to account for the presence of

1 non-POTS loops, except through the imprecise (and often-criticized, by Dr. Tardiff and
2 others) method of counting voice grade equivalents (VGEs). The development of more
3 advanced modeling and database techniques, and the availability of the ILECs' own
4 customer address databases, allow HM 5.3 to model such loops.

5 Dr. Tardiff's superficial comparison of the results of different model versions does not
6 consider or discuss such changes in modeling capabilities. Given his predisposition that
7 higher cost results are more accurate, he implicitly indicts the model for such advances.
8 But these changes are reasonable and in line with the FCC's guidelines. Furthermore, the
9 right way to assess HM 5.3 is to review the assumptions, techniques, and inputs in that
10 model, not to draw comparisons with earlier versions of the model that were subject to
11 the limitations that existed when they were developed.

12 Incidentally, it is telling that Dr. Tardiff finds that the HM 5.3 loop investments are
13 higher than those in predecessor versions when comparable price inputs are used. One
14 would expect this: when the model is accounting for more loop types, and thus more
15 capacity, total investments should increase. What he does not seem to realize, or at least
16 acknowledge, however, is that, barring any other model changes, the per-POTS-line
17 investments might actually decrease due to the increased sharing of structure and cables
18 that is now reflected in the Model.

19 **Q. DR. TARDIFF MAKES LIGHT OF YOUR EMPHASIS ON MODEL**
20 **INTEGRATION (PP. 64-66). PLEASE COMMENT ON HIS ASSESSMENT.**

21 A. I have a number of comments about the importance of integrating UNE calculations in a
22 single model. First, Dr. Tardiff does not discuss two of the primary benefits of

1 integration. The first of these is that by integrating the calculation of investments and
2 expenses for all portions of the exchange network, the Model can make available the
3 results of calculations done in one stage of a model to modules that required those results
4 in later stages of the Model's flow. This avoids the potential for transcription errors in
5 moving results from one module to another; further it minimizes the effort required to set
6 common model inputs such as cost of capital and the level of support expenses. The
7 second is that integration ensures investments and costs associated with different UNEs
8 are calculated once and assigned to UNEs in a fashion that ensures the amounts involved
9 are neither under-counted nor over-counted.

10 Dr. Tardiff attributes the use of a single set of interoffice plant structure percentages,
11 instead of different figures by density zone, as a failure to properly integrate the Model.
12 It is nothing of the sort. Interoffice percentages could have been done on a per-density-
13 zone basis. However, it was the judgment of the outside plant advisors to the HAI Model
14 that such a degree of granularity would contribute little to the overall accuracy of the
15 results produced by the Model, particularly since interoffice costs are not deaveraged by
16 density zone. Cost models obviously involve many tradeoffs between complexity and
17 accuracy, and this judgment was one such tradeoff. Furthermore, interoffice routes often
18 do not run through areas where no customers are located, so integration would not have
19 yielded all the data necessary to do such a breakdown in any case.

20 Dr. Tardiff points out that by using a single representative density zone to set the
21 interoffice structure percentages, the Model is assuming too little of the interoffice
22 facilities are placed in conduits in urban areas. True enough – and, likewise, it also is
23 putting too much into conduits in rural areas where the bulk of the interoffice facilities

1 are likely to be located due to the long distances between wire centers. That is the nature
2 of an average – it exceeds members of the averaged population in some cases, and is less
3 that other members of the population.

4 Dr. Tardiff also criticizes the use of “assumed” amounts of overlapping structures – for
5 instance, the amount of sharing between feeder and distribution routes. The
6 “assumptions” to which he is referring are the reasoned judgments of the outside plant
7 expert advisors to the HAI Model team. The amount of sharing is a user-adjustable
8 parameter that can be changed if users have cause to believe the HAI outside plant
9 experts are wrong. Dr. Tardiff himself discusses how he has done sensitivity runs in
10 which he has changed the assumed sharing percentages. In the process of commenting
11 on the results of these analyses, he puts himself in the odd position of criticizing the
12 amount of sharing assumed by the Model and then turning around and criticizing the
13 Model for not showing a larger effect of sharing.

14 **Q. STARTING IN HIS DISCUSSION OF INTEGRATION, AND CONTINUING ON**
15 **TO A MORE GENERAL DISCUSSION OF MODEL SOPHISTICATED, DR.**
16 **TARDIFF CLAIMS THAT THE MODEL IS NOT AS SENSITIVE TO VARIOUS**
17 **CHANGES AS ONE MIGHT EXPECT (TARDIFF, PP. 66-68). ARE DR.**
18 **TARDIFF’S CLAIMS CORRECT?**

19 A. No. In the first place, it is interesting how Dr. Tardiff interprets the motives of the HAI
20 Model developers for including integration in the Model:

21 Dr. Mercer’s emphasis on integration stems from his apparent belief that
22 there are large savings to be had when different components of the
23 network (e.g., feeder and distribution) share structure (e.g., telephone
24 poles and buried trenches). (Tardiff, p. 66)

1 Dr. Tardiff has no ability to interpret my motives or those of the rest of the HAI Model
2 team. In fact, the Model assumes sharing of various kinds because the outside plant
3 experts have emphasized that kind of sharing is done in the real world. Obviously, if we
4 wanted investments to drop a lot, we would simply set the various sharing percentages at
5 100%, or assume a more aggressive degree of sharing, and be done with it. Alternatively,
6 if we were results-oriented, we could have simply dropped the structure sharing features
7 of the Model when we were disappointed with the results. Instead, we have used the
8 reasoned judgment of experts who know about such matters, whether that produces
9 effects that meet Dr. Tardiff's expectations or not.

10 Second, Dr. Tardiff's arguments are a prime example of conclusions he makes without
11 basis, and without even disclosing what he believes to be the right answer. Dr. Tardiff is
12 apparently sure structure sharing should have a much bigger effect than it does.

13 Likewise, he apparently knows terrain factors (bedrock depth and hardness, water table
14 depth, soil types) should have a bigger impact than they do. Nowhere does he say what
15 he believes the impacts should be, or why they should be of that magnitude.

16 Nevertheless, on the basis of his unstated beliefs, and the Model's failure to meet them,
17 he is able to state that the Model's optimization features are "dubious" and that the such
18 modeling features are "flawed." (Tardiff, p. 68)

19 Perhaps Dr. Tardiff's intended point is that it is not important to build an integrated
20 model because the HM 5.3 loop results are not very sensitive to the issues that integration
21 addresses anyhow. If that is his point, I still disagree with him. Neither he nor I nor this
22 Commission could have known how much the Model's results were sensitive to the

1 various sharing factors until the Model was run. Thus integration plays an important role
2 because without it the sensitivities would not be known.

3 Third, in concluding the Model is flawed because it seems insensitive to the changes he
4 has made, Dr. Tardiff has used the wrong measure of sensitivity. He has reported only
5 the total loop cost. The loop cost is the sum of many contributing factors, including the
6 NID, drop, terminal and splice, distribution and feeder cable, digital loop carrier common
7 equipment and plug-in cards, and the distribution and feeder structure. It is not
8 surprising, then, that the total cost is not highly sensitive to changes in any one factor. To
9 appropriately test the effects of changing the amount of structure sharing, or any other
10 model factor, one should therefore look at the specific investment (or cost) impacted by
11 the change.

12 I have repeated two of the sensitivity analyses Dr. Tardiff has identified: I have changed
13 the amount of feeder-interoffice sharing from 75% to 0%, and, separately, the amount of
14 feeder-distribution sharing from 55% to 0%. In these two runs, I have, respectively,
15 examined the amount of feeder plus interoffice structure investment and the amount of
16 feeder plus distribution structure investment, in both cases considering the type of
17 structures that can be shared. The results are shown in the following table – the
18 investments change by 14.2 percent and 5.2 percent, respectively. Obviously, the amount
19 of assumed structure sharing has a substantial impact on the Model’s results for the
20 relevant investments.

	Feeder-Distribution Sharing Reduced To 0%	Feeder-Interoffice Sharing Reduced To 0%
--	----------------------------------------------	---------------------------------------------

Relevant Structure Investment	Feeder plus Distribution	Feeder plus Interoffice
Investment Before Change	\$90,359,486	\$68,481,686
Investment After Change	95,080,957	\$79,783,328
Investment Change	4,721,471	\$11,301,642
Percentage Change	5.2%	14.2%

I have not analyzed the sensitivity of the outside plant structure investment to the “most favorable [terrain] conditions everywhere,” as Tardiff names that particular study (Tardiff, p. 68). When he made a similar claim in a Massachusetts proceeding, however, I did a sensitivity analysis that showed the statewide outside plant placement costs were 14.7% higher for the terrain conditions assumed in the Model than for the most favorable terrain conditions.⁵ This is not a negligible impact, considering that unfavorable terrain conditions exist only in a portion of the state of Massachusetts.

Q. DR. TARDIFF CLAIMS THAT WHEN HE USED THE NEW CAPABILITY OF HM 5.3 TO LIMIT SAI SIZE, THE EFFECT ON THE RESULTS WAS NOT WHAT AT&T JOHN DONOVAN HAD CLAIMED THE WOULD BE IN THE SBC-CALIFORNIA PROCEEDING (TARDIFF, P. 69) CAN YOU COMMENT ON THIS FINDING?

⁵ Investigation by the Department of Telecommunications and Energy on its own Motion into the Appropriate Pricing, based upon Total Element Long-Run Incremental Costs, for Unbundled Network Elements and Combinations of Unbundled Network Elements, and the Appropriate Avoided Cost Discount for Verizon New England, Inc. d/b/a Verizon Massachusetts’ Resale Services in the Commonwealth of Massachusetts, D.T.E. 01-20, Surrebuttal Testimony of Dr. Robert A. Mercer, December 17, 2001, p. 21.

1 A. Yes. The capability to which Dr. Tardiff is referring was a special feature added to the
2 Model for testing purposes. It was not intended for use in Washington, but instead of
3 recoding the Model to eliminate it, we simply turned it off in the user interface.
4 Unfortunately, it was only turned off, not disabled, meaning a user could turn it on again.
5 I unintentionally exacerbated that problem by describing the feature in the HM 5.3 Model
6 Description submitted as Attachment RAM-4 to my Supplemental Direct Testimony.

7 When the feature is invoked, as Dr. Tardiff has done, the calculation requires a table that
8 is not populated in the version of the Model submitted in this proceeding. Therefore, the
9 Model produces erroneous results. The solution is simple – turn this feature off, as it was
10 turned off when originally filed with the Commission.

11 **Q. DR. TARDIFF SUPPORTS MR. MURPHY’S FINDING THAT BECAUSE THE**
12 **MODEL UNDERSTIMATES THE NUMBER OF HIGH-RISE BUILDINGS, IT**
13 **REDUCES COSTS BY SUBSTITUTING LOW-COST AERIAL DISTRIBUTION**
14 **STRUCTURES FOR COSTLY UNDERGROUND FEEDER FACILITIES IN**
15 **HIGH DENSITY AREAS (TARDIFF, P. 72). IS THIS A VALID CRITICISM?**

16 A. No, it is nonsensical. Whether a cluster is identified as a high-rise building or not, feeder
17 is extended from the wire center to the centroid of the cluster. The amount of feeder and
18 the type of supporting structure for that feeder is determined by the density zone to which
19 the cluster belongs, not by the nature of the subsequent distribution cable.

20 What does happen as a result of not identifying all the high rise buildings is that regular
21 distribution cable is then used instead of riser cable. Inasmuch as the riser cable
22 investment should not be considered to be part of the loop, while distribution cable

1 clearly is part of the loop, this means that, if anything, the Model is overestimating the
2 amount of distribution investment required.

3 **Q. DR. TARDIFF SEEMS TO TAKE ISSUE WITH THE FACT THAT**
4 **“ALTHOUGH THE [STRAND DISTANCE NORMALIZATION] OPTION WAS**
5 **INTRODUCED TO ADDRESS REGULATORS’ CONCERNS ABOUT**
6 **INSUFFICIENT FACILITIES IN LOW-DENSITY AREAS (THUS PRODUCING**
7 **COSTS THAT ARE TOO LOW), USING THE OPTION HAS TYPICALLY**
8 **REDUCED THE ESTIMATED COSTS IN HIGHER DENSITY AREAS.”**
9 **(TARDIFF, P. 74). IS THERE ANYTHING INCONSISTENT WITH THESE**
10 **TWO RESULTS?**

11 A. No. The strand distance normalization option was added to the Model for the reason Dr.
12 Tardiff mentioned: concern that by distributing building lots uniformly in rural areas, the
13 Model might not produce enough strand distance (because the effective lot sizes
14 determined by the Model may be so large in clusters with small numbers of lines that in
15 effect customers are placed too far from the borders). The strand distance normalization
16 process fixes this problem. On the other hand, in residential and urban areas, customers
17 are often not distributed uniformly throughout a cluster, due to parks, school grounds,
18 undeveloped land, and (in dense urban areas) parking garages, plazas, and other
19 unoccupied areas. In such cases, customers are in effect concentrated into one or more
20 “sub-clusters” that tends to reduce the amount of cable required to reach them.
21 Appropriately, then, strand normalization tends to reduce, not increase, the amount of
22 route miles required to connect all customers to the SAI.

1 Dr. Tardiff has not identified any reason why this is an odd or unexpected result, nor does
2 he indicate that there is a problem with the Model. Thus when Dr. Tardiff says:

3 More importantly, if anything, HM 5.3's use of the strand distance makes
4 the distribution clusters less representative of the areas in which Verizon
5 NW's actual customers live. . . .

6 The Model's MST adjustment only serves to further distort the clusters
7 modeled by HM 5.3. . . .

8 As a result, the MST adjustment distorts all of the clusters (and implicitly
9 the customer locations within the clusters) modeled by HM 5.3 (Tardiff,
10 pp. 74-75),

11 and then goes on to claim

12 For example, when the MST adjustment calls for less cable than the
13 Model would have provided absent the adjustment, the rectangular clusters
14 are compressed along both dimensions. In the process, customers are in
15 effect packed into smaller, higher density lots. Conversely, when the
16 strand distance exceeds the calculated route distance, the cluster in effect
17 expands and potentially overlaps with adjoining clusters. . . .

18 In the process, the Model either shrinks or expands the entire grid (cable
19 sizes and all), with no regard as to how the locations originally included in
20 the cluster could actually be connected, (Tardiff, pp. 75-76)

21 he is dramatically mischaracterizing the purpose of strand normalization. Normalization
22 is neither intended to shrink or expand the distribution areas, but to better capture where
23 customers are actually located within the clusters that have been defined. For instance,
24 when a strand normalization factor is greater than unity in a rural area, it does not mean
25 the cluster area has grown. Rather, it means that the Model has originally assumed
26 customers are closer together within the cluster than they actually are. By invoking
27 normalization, the Model correctly calculates the amount of cable required to reach their
28 actual locations. Dr. Tardiff is in the inconsistent position of having criticized the
29 assumption that customers are uniformly distributed within a cluster, and then turning

1 around and criticizing the modeling process that specifically addresses and eliminates this
2 concern.

3 **Q. DO YOU AGREE WITH DR. TARDIFF THAT VERIZON’S VZLOOP MODEL**
4 **“PRODUCES A MUCH MORE REALISTIC REPRESENTATION OF THESE**
5 **ROUTES THAN DOES HM 5.3’S ABSTRACT ‘GRILLS’” (TARDIFF, P. 76)?**

6 A. Not at all. The effect of strand normalization is to match the modeled distribution route
7 miles to a realistic representation of the amount of cable required to connect customers
8 (along right angle paths to add enough cable to accommodate geographic obstacles and
9 other routing impediments) to each other and the SAI. Verizon ostensibly starts from
10 actual terminal locations. But it then connects those locations assuming straight-line
11 routing, which is not at all a realistic representation of the amount of cable required to
12 reach customers.

13 Dr. Tardiff’s claim that in the real world, cables are routed to fit the “unaltered layout of
14 a distribution area,” whereas HM 5.3 expands and contracts the serving areas, is
15 nonsense. The whole point of the strand normalization process is to better determine
16 where customers are located so appropriate amounts of cable can be used to reach them.
17 The right way to think of this process, notwithstanding Dr. Tardiff’s comments to the
18 contrary, is that the model makes an initial estimate of where customers are located and
19 how much cable is required using the backbone and branch grids, then refines the cable
20 estimates using the strand normalization. The process does not shrink or expand the area
21 where customers are located; rather, it effectively increases or decreases the amount of
22 cable required in response to better estimates of the customer locations.

1 **Q. DR. TARDIFF CLAIMS THAT THE MAXIMUM ANALOG COPPER**
2 **DISTANCE SHOULD BE CHECKED, AND THE COPPER VERSUS FIBER**
3 **FEEDER DECISION MADE, USING POST-NORMALIZATION DISTANCES**
4 **RATHER THAN PRE-NORMALIZATION DISTANCES (PP. 77-78). IS THIS AN**
5 **APPROPRIATE APPROACH?**

6 A. Although his proposal is caught up in erroneous rhetoric about the expansion and
7 compression of serving areas that is taking place, Dr. Tardiff's proposal may have merit,
8 subject to further examination. To the extent the strand normalization factor is greater
9 than unity for a cluster, it suggests customers are more spread out than the backbone and
10 branch calculations originally assume. That being the case, it makes sense to check the
11 need to deploy fiber feeder and potentially subdivide clusters using the post-
12 normalization, rather than pre-normalization, distances.

13 Given the limited time available since Dr. Tardiff's testimony was filed, we have not yet
14 been able to test the Model with such a change properly implemented. However, we
15 have been able to do a strict upper-bound check of the effect by assuming distribution
16 cable runs all the way to the corners of the cluster, whether strand normalization indicates
17 it should run that far or not. When this is done, the average loop cost increases on the
18 order of \$0.20, or approximately a 2.5% increase.

19 **Q. DR. TARDIFF FINDS IT PECULIAR THAT THE OPTIMIZED SET OF**
20 **INTEROFFICE RINGS DOES NOT CHANGE WHEN THE RELATIVE**
21 **CIRCUIT DEMAND OF DIFFERENT WIRE CENTERS IS ALTERED**
22 **(TARDIFF, P. 80). DOES THAT LACK OF VARIABILITY SURPRISE YOU?**

1 A. Not really. The optimization process considers the optimum physical ring structure – that
2 is, the way interoffice fiber cables are routed from wire center to wire center. The
3 number of logical rings implemented on those physical rings is determined in a later stage
4 of the IOF calculations. Thus the ring optimization outcome is dominated by the relative
5 costs of different possible physical route arrangements, which in turn are most influenced
6 by the geographical layout of the wire centers (which doesn't change just because
7 demand changes). The amount of multiplexing required in the wire centers where
8 different rings interconnect is a secondary consideration, but the variability in the
9 multiplexing costs associated with ring interconnection is generally much less than the
10 variability in facilities costs (outside plant structures and cabling) that can occur when
11 routes are changed.

12 **Q. DR. TARDIFF APPARENTLY FINDS IT SURPRISING THAT THE ASSUMED**
13 **FRACTION OF HIGH CAPACITY LOOPS REQUIRING INTEROFFICE**
14 **CIRCUITS HAS A RELATIVELY SMALL IMPACT ON TOTAL RING COST**
15 **OVER A CONSIDERABLE RANGE OF INTEROFFICE CIRCUIT COUNTS,**
16 **AND THEREFORE A HIGH IMPACT ON THE COST PER CIRCUIT**
17 **(TARDIFF, P. 82, TABLE 9). IS THIS SURPRISING?**

18 A. No, it is not. There are considerable “economies of scale” in the interoffice network,
19 because there are large fixed costs – outside plant structures, fiber cable (the Model
20 automatically deploys a 24-strand cable at a minimum), and the fixed part of the circuit
21 equipment investment – and relatively small costs to add circuits to this fixed investment.
22 Therefore, the behavior depicted in Tardiff's Table 9 is exactly what one would expect –
23 adding circuits increases total investments somewhat, but the cost per circuit goes down.

1 This misapprehension on Dr. Tardiff's part is another example of his pre-conceived
2 notion of what a result should be, lacking any supporting evidence or even a rationale for
3 holding that view. And in spite of that lack of a basis for his opinion, it leads him to the
4 inaccurate description of the "Model's insensitivity to many aspects of ring design"
5 (Tardiff, p. 81), and of "the shaky foundations of HM 5.3's interoffice calculations
6 [that]produce results that defy common sense" (Tardiff, p.82)

7 **Q. BUT DOESN'T DR. TARDIFF ACKNOWLEDGE THE ECONOMIES OF SCALE**
8 **IN THE INTEROFFICE NETWORK, AS DISCUSSED ON P. 82 OF HIS**
9 **TESTIMONY?**

10 A. Yes, but he does so in the context of claiming that the cost per DS-3 IOF circuit should
11 be less than the cost of a DS-3 loop, because of the economies of scale in the interoffice
12 network. What this comparison misses is that there are both economies of scale and
13 scope in the loop. Every component of the cost incurred by a DS-3 loop, with the
14 exception of the termination equipment at the customer's premises, is shared with the
15 provision of POTS service. There are a lot of POTs loops that consume a large share of
16 structure and cable costs. Thus the fixed cost of an increment of DS-3 loops may well be
17 substantially less than the fixed cost of an increment of DS-3 IOF circuits. Since the
18 relationship of the two costs is a complex function of so many factors, there is no way Dr.
19 Tardiff or anyone else can know *a priori* what the resulting cost relationship should be –
20 that is the value of cost models.

21 **Q. DR. TARDIFF IDENTIFIES PROBLEMS WITH THE INTEROFFICE**
22 **CALCULATIONS IN EARLIER VERSIONS OF THE HAI MODEL IN THE**
23 **PROCESS OF SAYING IT IS NOT SURPRISING THE CURRENT VERSION'S**

1 **INTEROFFICE CALCULATIONS ARE IN ERROR (TARDIFF, PP. 83-84).**

2 **HOW DO YOU RESPOND TO THIS DISCUSSION?**

3 A. First of all, when all is said and done, Dr. Tardiff has not demonstrated a single *bona fide*
4 problem with the IOF calculations in HM 5.3. Rather, he has demonstrated the danger of
5 making *a priori* assumptions that don't withstand scrutiny, then sticking to those
6 assumptions even after they prove to be wrong.

7 More importantly, he is off the mark with respect to the key lesson to be gleaned from the
8 discovery and correction of problems in earlier versions of the Model. That lesson is that
9 throughout the history of the HAI Model, its developers have put the Model out for
10 public scrutiny, invited feedback, and responded to constructive criticisms by making
11 necessary corrections. The Model is better as a result of that process, and the fact that
12 corrections were made in the past is not evidence there are still corrections to be made.
13 By contrast, the Verizon model is new, untested, and prone to the many errors Mr. Steven
14 Turner describes in his testimony on behalf of AT&T.

15 **Q. WHAT IS YOUR REACTION TO DR. TARDIFF'S ASSERTION THAT**
16 **SWITCHING COSTS SHOULD REFLECT THE COST OF PROVIDING**
17 **GROWTH LINES AS WELL AS PURCHASING NEW SWITCHES (TARDIFF, P.**
18 **84)?**

19 A. TELRIC is designed to estimate the cost of providing the current level of demand, with
20 excess capacity for near-term growth. Through the switch administrative fill factor, HM
21 5.3 provides a modest amount of capacity for near-term growth. Including the cost of
22 capacity needed to serve future demand at allegedly higher prices would unfairly and
23 uneconomically burden today's customers. Because of the way the Model calculates

1 capital costs, the current ratepayers would be paying the higher growth prices over the
2 lifetime of the switch, even though they are not the beneficiaries of that growth. I do not
3 see why this would be an any more reasonable course of action than it would be to
4 anticipate future price increases in any other part of the network.

5 Further, it should be kept in mind, that any growth experienced by Verizon implies that
6 Verizon will be receiving revenues from this growth. Dr. Tardiff's solution seems to be
7 that the cost of growth should be paid for by current demand and the revenue Verizon
8 experiences from growth simply falls into the pockets of Verizon. In other words, Dr.
9 Tardiff's solution would be for Verizon to double recover the cost of any growth lines.

10 **Q. HAS DR. TARDIFF OFFERED ANY EVIDENCE THAT LINES FOR GROWTH**
11 **ARE MORE EXPENSIVE THAN LINES IN NEW SWITCHES?**

12 A. He offers as evidence only an old document that HAI Model developers used back in the
13 late 1990's to develop switch prices. He offers no evidence that Verizon would today
14 have to pay any more for new lines than for growth lines.

15 **Q. DR. TARDIFF CLAIMS THAT BASED ON THE HAI MODEL SWITCHING**
16 **DESIGNS SWITCHES WOULD HAVE TO BE REPLACED MORE**
17 **FREQUENTLY THAN THE CURRENT DEPRECIATION RATES (TARDIFF, P.**
18 **85). IS THIS CORRECT?**

19 A. No, Dr. Tardiff clearly does not understand the HM 5.3 switch design. The Model assumes
20 that switches placed have an ultimate capacity of 120,000 lines (this is a user adjustable
21 input). Tardiff seems to believe that the switches in HM 5.3 are deployed at 94% of their
22 ultimate capacity. This is not the case. The Model will add switches whenever the line

1 demand exceeds the input maximum line size, adjusted for fill. Currently the maximum
2 switched lines in any Verizon office is 78,167. This leaves room for 34,633 additional
3 lines ($120,000 * .94 - 78,167$). This is a 44% increase over the current lines in this office.

4 Dr. Tardiff further implies that based on the HM 5.3 design, switches would have to be
5 replaced each year for technological advances. Again this is false. Switches do not need
6 to be scrapped every time there is a new technological development. The GR-303
7 interface is a particularly relevant example. When new interface standards for
8 transmission or loop equipment become available, switch vendors develop new interfaces
9 for their switches that are compatible with the standard. Lucent's predecessor, Western
10 Electric, for example, didn't scrap the 5ESS design when the first TR-303 interface
11 requirements were specified (sometime after the 5ESS commercial introduction), nor did
12 the 5ESS design become obsolete when standards became available to allow the
13 development of an integrated SONET OC-3 trunk interface. The switch development
14 organization just set about the task of designing an interface that allows the switch
15 control and fabric to accommodate the new external service.

16 **Q. DR. TARDIFF CLAIMS THAT HM 5.3 DOES NOT INCORPORATE THE FCC'S**
17 **SWITCH COST COMPUTATION (TARDIFF, P. 87). IS THAT CORRECT?**

18 A. This is a misleading claim. The FCC's switch cost "computation" is the same as the
19 HM5.3 calculation. What Dr. Tardiff is referring to is the DLC line offset input. The
20 FCC believes the value of this input should be zero; AT&T does not agree for the reasons
21 stated in the HM 5.3 Inputs Portfolio, Attachment RAM-5 do my Supplementary Direct
22 Testimony. Just because HM 53. uses a different input value than the one set in the FCC

1 model does not make the computation different – this is just Dr. Tardiff’s usual blurring
2 of the distinction between a model platform and the model’s inputs.

3 **Q. ACCORDING TO DR. TARDIFF, THERE IS NO LOGICAL REASON TO**
4 **ASSUME THAT A REDUCTION IN NETWORK INVESTMENTS WOULD**
5 **AUTOMATICALLY IMPLY THAT AN EFFICIENT FIRM COULD**
6 **PROPORTIONATELY REDUCE ITS NETWORK OPERATIONS EXPENSES**
7 **(TARDIFF, P. 90, EMPHASIS ADDED). HOW DO YOU RESPOND TO THIS**
8 **STATEMENT?**

9 A. I agree with Dr. Tardiff – there is no *a priori* reason to assume a linear relationship
10 between the level of network investment and the level of network operations expenses.
11 Instead, one should undertake the appropriate analysis. Just such an analysis was
12 undertaken by AT&T/MCI witnesses Thomas Brand and Arthur Menko in the Verizon of
13 California proceeding.. They showed that there is a very strong correlation of network
14 operations expenses with total network investment over a wide range of companies they
15 considered. On that basis, HM 5.3 as submitted in the Verizon of California UNE
16 proceeding and this proceeding use the results of their analysis.

17 **Q. PLEASE COMMENT ON DR. TARDIFF’S ASSERTION THAT IT IS**
18 **UNREASONABLE TO CALCULATE CORPORATE OVERHEAD EXPENSES**
19 **AS A PERCENTAGE OF TOTAL EXPENSES CALCULATED BY THE MODEL.**

20 A. Again, the Brand-Menko testimony in California is instructive. They showed that there is
21 a high degree of correlation of corporate overhead expenses to total company expenses
22 minus corporate overhead (cite Brand-Menko, Section VI.C). This is the form of the
23 calculation of corporate overhead expenses that has been used in this proceeding.

1 **Q. DOES DR. TARDIFF PRESENT A BALANCED PICTURE OF THE**
2 **TREATMENT OF THE HAI MODEL BY STATE REGULATORY AGENCIES?**

3 A. No, he does not. He mentions that the Model has been rejected in several states. He does
4 not, however, mention that

- 5 • The states he identified rejected earlier versions of the Model, not HM 5.3;
- 6 • HM 5.2a, the predecessor to HM 5.3 was adopted in Arizona, Colorado,
7 Minnesota and Utah; and
- 8 • The CPUC Staff’s Proposed Decision rejects both HM 5.3 and the SBC-
9 California models, but does so in terms that are closely aligned with the positions
10 that AT&T has taken in this proceeding in a large number of instances. In
11 particular, the Proposed Decision rejects many of the same claims by SBC-
12 California against HM 5.3 that Dr. Tardiff and other Verizon witnesses have made
13 in this proceeding.

14 **III. RESPONSE TO THE TESTIMONY OF CHRISTIAN M. DIPPON**

15 **Q. PLEASE SUMMARIZE THE NATURE OF MR. DIPPON’S TESTIMONY**
16 **ABOUT HM 5.3**

17 A. Mr. Dippon addresses the processes used to produce the customer location database for
18 HM 5.3. According to Mr. Dippon, the customer location database is flawed to the point
19 that this Commission cannot properly use HM 5.3 to estimate Verizon’s UNE costs. He
20 categorizes these flaws as conceptual, technical, and factual. Conceptually, Mr. Dippon
21 says, the Model develops cost estimates for a “utopian network” that even AT&T/MCI
22 admit cannot realistically be built. Technically, Mr. Dippon asserts that the cost

1 estimates developed by HM 5.3 do not demonstrate sensitivities they should possess.
2 Factually, Mr. Dippon alleges that maps of the outside plant network modeled by HM 5.3
3 show that the Model produces cost estimates that are entirely unrealistic.

4 **Q. PLEASE SUMMARIZE YOUR OVERALL RESPONSE TO MR. DIPPON’S**
5 **CRITICISMS OF THE HM 5.3 DATABASE AND THE PROCESS THAT**
6 **PRODUCED IT.**

7 .A. In the first place, Mr. Dippon uses extreme statements in an apparent effort to distract the
8 Commission from analyzing the merits of his arguments. Thus, Mr. Dippon claims the
9 Model produces a “fantasy network design” (Dippon, p. 3); it is an “artifice to obtain
10 Verizon’s NW’s UNEs at a fraction of their forward-looking cost” (*id.*); it develops costs
11 for “a utopian network that even ATT/MCI admit cannot realistically be built” (Dippon,
12 pp. 3-4); and it produces cost estimates that are “predominately driven by the overly
13 simplistic and arcane modeling assumptions embedded in the modules that determine
14 HM 5.3’s outside plant network” (Dippon, p. 5). Such statements are devoid of
15 substance.

16 Second, Mr. Dippon, like Dr. Tardiff, has preconceived notions about sensitivities the
17 Model should possess. Not surprisingly, the thrust of many of these preconceptions is
18 that costs should increase when certain changes are made. When those increases fail to
19 materialize, he concludes it must be the Model that is flawed, rather than his
20 preconceptions. In at least a couple of cases, he has previously stated these
21 preconceptions in the SBC-California proceeding, yet notwithstanding the fact that it was
22 demonstrated why his preconceptions are misguided, he repeats them here.

1 Third, by Mr. Dippon’s implications, the supposed failings of the model are equally
2 draconian in their impact on the Model. Mr. Dippon apparently believes that each
3 individually is cause to reject the Model and that none have small or non-existent impact
4 on the results produced by the Model. Such contentions on their face are simply not
5 realistic.

6 Finally, Mr. Dippon’s criticisms demonstrate an unreasoned bias in favor of his client’s
7 VzLoop model, a bias, I might add, that is shared by Mr. Murphy (Murphy, p. 21). Thus,
8 according to Mr. Dippon,

9 maps of VzLoop’s modeled outside plant demonstrate how VzCost, unlike
10 HM 5.3, follows feasible network routes by generally avoiding physical
11 obstacles and boundaries, accounting for rights-of-way, and thereby
12 producing representative investment estimates of a forward-looking
13 network in the State of Washington (Dippon, p. 6).

14 This is a misleading statement, because as I have already pointed out, Verizon’s cost
15 modelers admitted during a workshop in the Verizon of California workshop that all
16 routes are based on straight line segments between terminals. The resulting routing is so
17 overly optimal that it cannot be “avoiding physical obstacles and boundaries,” or
18 “accounting for rights-of-way.” Indeed, as Mr. Dippon himself finds, HM 5.3 produces
19 more route miles than does VzLoop, precisely because it allows extra route miles to
20 bypass obstacles and accounts for the non-linearity of many rights-of-way. Therefore,
21 while Mr. Dippon can produce impressive maps that show the terminal locations assumed
22 by VzLoop follow roads and rights-of-way, the same is not true of the routes connecting
23 those locations.

24 **Q. DO YOU AGREE WITH MR. DIPPON’S CHARACTERIZATION THAT “HM**

1 **5.3 ASSUMES THAT VERIZON NW’S CUSTOMERS ARE UNIFORMLY**
2 **SPREAD IN RECTANGULAR-SHAPED DISTRIBUTION AREAS—AN**
3 **ASSUMPTION THAT IS ENTIRELY DIVORCED FROM REALITY (DIPPON,**
4 **P. 3)?**

5 A. No. This statement completely ignores the important role played by the strand
6 normalization process, as described in Section 8.4 of the HM 5.3 Model Description.
7 That process is designed to ensure the amount of distribution cable reflects the actual
8 locations of customers within the clusters, to the extent they are not uniformly distributed
9 in the cluster.

10 **Q. MR. DIPPON STATES THAT “MOST OF THE CRITICAL DATA THAT HM 5.3**
11 **USES TO DETERMINE QUANTITIES” IS “HARD-CODED IN THE CLUSTER**
12 **INPUT DATABASE, AND IS THE RESULT OF AN ENORMOUS AMOUNT OF**
13 **UNVERIFIABLE, LARGELY UNDOCUMENTED, AND CONVOLUTED**
14 **PREPROCESSING STEPS THAT ARE DONE OUTSIDE THE MODEL BY TNS”**
15 **(DIPPON, PP. 7-8). IS THIS AN ACCURATE CHARACTERIZATION?**

16 A. No. In the first place, it is a considerable overstatement to claim the cluster database
17 contains most or all of the data used by the Model. The Model also uses the distance file
18 that contains the location of each Verizon wire center, information from the Local
19 Exchange Routing Guide that, for instance, describes the type of each switch in the
20 network and which tandem switch each local switch homes on, ARMIS data on traffic
21 volumes and operating expenses, and a database containing the values of more than 2,100
22 user inputs.

1 Second, the database is not the product of “unverifiable, largely undocumented, and
2 convoluted preprocessing steps.” Mr. Dippon has had an extensive opportunity to be on-
3 line with TNS in order to understand the processing steps that have produced the
4 database. Notwithstanding his claim that he was “denied access to the clustering source
5 code, and in general ha[s] had to rely on very limited information as to the functioning
6 and objectives of many other files” (Dippon, p. 11), his knowledge is extensive enough
7 that he has been able to create a new cluster database on his own and successfully run
8 HM 5.3 using that database.

9 Third, the statement is entirely one-sided in not acknowledging the extreme amount of
10 pre-processing involved in the Verizon models as well. In an era of complex models,
11 with their sophisticated calculations on state-of-the art databases, I believe it is inevitable
12 that pre-processing of data will be necessary. Were it not done, it would take many hours
13 to perform each run of the Model. The issue is not with pre-processing per se, it is with
14 access to those pre-processing steps by parties to the proceeding. I believe Mr. Dippon
15 has had such access.

16 The SBC-CA Proposed Decision agrees with me on the necessity of pre-processing steps
17 and on Mr. Dippon’s access to the TNS processes:

18 In response, [Joint Applicants] contend that SBC-CA was given
19 everything it needed to review, understand, and test the TNS clustering
20 process. (JA, 3/12/03, p. 51.) We agree with [Joint Applicants] that it
21 provided reasonable access to its clustering process since SBC-CA’s
22 witness Dippon was able to run his own clustering scenario where he
23 reduced the maximum lines in the cluster from 6,451 to 1,800. (SBC-
24 CA/Dippon, 2/7/03, p. 42.) While the clustering algorithm was performed
25 by TNS as an outside input to HM 5.3, it is comparable to SBC-CA’s
26 preprocessing of its loop records before they were input to LoopCAT. In
27 other words, both parties had to “preprocess” vast amounts of data to

1 prepare it for input to the actual UNE cost models, and there are aspects of
2 both the TNS and the LoopCAT preprocessing work that outside parties
3 and Commission staff are not able to replicate or scrutinize for various
4 reasons. Nevertheless, [Joint Applicants] did describe the TNS clustering
5 process in some detail in its filings and through discussions with SBC-CA,
6 and SBC-CA was evidently provided enough information to be able to run
7 its own version to test a different set of clustering criteria (Proposed
8 Decision, pp. 72-73).

9 **Q. DO YOU AGREE WITH MR. DIPPON’S CHARACTERIZATION THAT “THE**
10 **MODELING DONE BY HM 5.3 IS MERELY THE FINAL STAGE OF AN**
11 **OBSCURE PROCESS THAT ESSENTIALLY STARTS WITH THE MODELED**
12 **NETWORK PLANT ALREADY IN PLACE (DIPPON, P.8, EMPHASIS ADDED)?**

13 A. No, Mr. Dippon cannot reasonably claim that the modeled network plant is already in
14 place in the TNS database. In fact, he goes even further, claiming

15 HM 5.3 merely fills-in-the-blanks . . . AT&T/MCI give the impression
16 that the outside plant modeled by HM 5.3 can be changed with user-
17 adjustable inputs. This is wrong. The preprocessing module largely
18 determines the layout (and hence the costs) of the modeled network, and
19 there is not a single user-adjustable input contained in HM 5.3 that is
20 capable of curing the network design produced by the Model’s extensive
21 preprocessing” (Dippon, p. 17).

22 There are any number of decisions and tasks left to be performed, and this is the
23 role of the HM 5.3 processing modules. For instance, what should the layout of
24 cable be – a single cable with enough capacity snaking around the entire cluster?
25 Multiple cables branching off main cables in a “tree and branch” arrangement like
26 HM 5.3 assumes? A spanning tree arrangement such as that assumed in the FCC
27 Synthesis Model? This decision has not been made in the customer location
28 database. How large should the cables be – just enough to meet current demand,
29 or should they contain some extra capacity? What gauge of cable should be used?
30 How much does a foot of cable cost? A foot of the supporting structure? Should

1 the cluster in question be served by copper or fiber feeder? There are hundreds of
2 such questions to be asked and answered. This is done in the HM 5.3 modules,
3 not the database. And the answers involve large numbers of the 2,100+ user
4 inputs, the values of which very much influence the design of the network –
5 contrary to Mr. Dippon’s characterization that “[a]t least in terms of the outside
6 plant configuration, the user-adjustable inputs are of little to no use” (Dippon, p.
7 18).

8 **Q. ACCORDING TO MR. DIPPON, THE LOTS MODELED BY HM 5.3 ARE**
9 **“ENTIRELY DIVORCED FROM THE ACTUAL LOCATIONS OF VERIZON**
10 **NW CUSTOMERS” (DIPPON, P. 14). DOES THAT CLAIM MAKE SENSE?**

11 A. No, it is an extreme overstatement, and meaningless at that. The Verizon customer
12 addresses are first geocoded – I assume Mr. Dippon would agree no such “divorce”
13 occurs at that point. They are then assigned to clusters that are no more than
14 approximately three miles on a side, and usually much smaller. The cluster locations are
15 determined by TNS – Mr. Dippon makes no claim and presents no evidence those
16 locations are stated in error. Within each small cluster, the customers are originally
17 distributed uniformly. Mr. Dippon may claim they may be moved in the process, but
18 they are certainly still within the confines of the cluster in which they were located.
19 Finally, since a properly-functioning cost model does not need to know the precise
20 location of any one customer, but the amount of dispersion between all the customers, the
21 Model further refines the amount of customer dispersion using a connectivity measure
22 determined from the original customer locations.

1 Where is the “divorce” in this process? Customers remain within the confines of the
2 small clusters to which they were originally assigned after being geocoded. Mr. Dippon
3 may be concerned that ultimately the precise location of any given customer is not
4 known, but ultimately only the relative positions of the customers, captured by the route
5 distance require to connect them, is required by the cost model.

6 **Q. PLEASE COMMENT ON THE CLAIM BY MR. DIPPON THAT “HM 5.3’S**
7 **MODELED NETWORK DOES NOT MODEL TO A SINGLE VERIZON NW**
8 **CUSTOMER LOCATION” (DIPPON, P. 18)**

9 A. Let me do so by reference to the pictures Mr. Dippon includes on pp. 81-82 of his
10 testimony. While Mr. Dippon uses these pictures to nitpick about certain anomalies he
11 claims exists, what they really show is that customer locations can be logically grouped.
12 The logical groupings – the clusters – are located where customers are located. The bulk
13 of these clusters can obviously be reasonably represented as rectangles. Customers are
14 located along roads in the cluster, not for instance in the water adjacent to the clusters.
15 The use of the strand distance – the amount of cable require to connect the customer
16 locations in a cluster – provides a useful measure of the number of cable route miles
17 required.

18 For the overwhelming number of customers shown in these pictures, the model is
19 working as it should. Mr. Dippon focuses on “anomalies,” but ignores the fact that the
20 exceptions prove the rule. As the pictures demonstrate, this is not a case of a glass being
21 half empty or half full – it shows the glass is a fraction of a percent empty or well over
22 99% full. And even in the case of the supposed anomalies, the model workshops in the

1 Verizon of California workshops demonstrated that the Verizon models, too, have their
2 own anomalies.

3 **Q. MR. DIPPON CLAIMS “VERY LITTLE INFORMATION GAINED FROM THE**
4 **ELABORATE GEOCODING AND SURROGATING EXERCISE, IF ANY AT**
5 **ALL, IS USED TO DERIVE THE FINAL UNE COST ESTIMATES (DIPPON, P.**
6 **19). IS THIS A CORRECT ASSESSMENT?**

7 A. No, not at all. First, it is amusing that the information on the location, size, and shape of
8 the clusters should be characterized by Mr. Dippon as “marginal.” This information
9 plays a key role in determining the amount of cable plant that will be deployed by the
10 Model. Beyond this basic information, however, there are any number of parameters
11 retained in the cluster database and used by the Model. These include the strand distance,
12 which is a key measure of customer dispersion, the number of lines of each type modeled
13 in HM 5.3, the number of households, the numbers of different kinds of buildings in
14 which those households are located, the number and size of businesses, and geological
15 considerations that will affect cost – bedrock depth and hardness, water table depth,
16 surface textures. These parameters play varying, but all important, roles in determining
17 the UNE estimates that are ultimately provided by the Model.

18 **Q. ACCORDING TO MR. DIPPON, REFERRING TO PICTURES SHOWN IN HIS**
19 **EXHIBIT CMD-6, “[THE] INCORRECT DETERMINATION OF THE**
20 **CENTROID’S LOCATION FURTHER DISTORTS THE DISTRIBUTION OF**
21 **DEMAND BECAUSE IT THEN MOVES CUSTOMER LOCATIONS ROUND A**
22 **FALSE CENTER POINT” (DIPPON, P. 20). IS THIS A VALID CONCERN?**

1 A. Not significantly. As Mr. Dippon notes, the Model assumes the rectangle representing a
2 given cluster is drawn centered on the SAI location. When the centroid of the cluster, as
3 defined by the TNS database, happens to fall on or near one edge of the cluster, this can
4 lead to a peculiar appearance – it appears the real cluster location has been shifted over to
5 a new location. However, this is only an appearance: from the point of view of
6 calculating distribution costs, it makes no difference where the rectangle is located. That
7 is, whether (1) the SAI was originally centered in the cluster, as Mr. Dippon suggests,
8 with backbone and branch cables emanating out from that location to reach the
9 boundaries of the cluster; or (2) the SAI is located at the centroid, which in an extreme
10 case is along the edge of the cluster, and all the points are conceptually picked up and
11 moved over the same amount so they are centered on the SAI, the distribution cost
12 calculations will still yield the same result.

13 The only potential impact on costs is that if SAIs were relocated from the centroid to a
14 center point of the cluster, as suggested by Mr. Dippon, the sub-feeder cables to those
15 SAIs would then be running to slightly different locations. This might cause feeder costs
16 to change slightly, but whether the net change would be upward or downward cannot be
17 know *a priori*. Thus, Mr. Dippon is wrong that the SAI location (or, as he sees it, mis-
18 location) has serious consequences.

19 **Q. ACCORDING TO MR. DIPPON, NOTHING MUCH HAS HAPPENED TO THE**
20 **MODEL’S ALGORITHMS BETWEEN VERSION HM 2.2.2 OF THE MODEL,**
21 **RELEASED IN 1996, AND VERSION 5.3 OF THE MODEL, EXCEPT, HE SAYS,**
22 **HM 2.2.2 MODELED SQUARE SERVING AREAS AND HM 5.3 MODELS**
23 **RECTANGULAR AREAS (DIPPON, P. 22) IS THIS AN ACCURATE**

1 **STATEMENT?**

2 A. No. It seriously misrepresents the numerous vast differences between HM 2.2.2 and HM
3 5.3, even with respect to the layout of plant, let alone many other aspects of the Model.
4 For example, the “square areas” in HM 2.2.2 were entire Census Block Groups. These
5 could be as large as 30 miles on a side, although most are much smaller. There was no
6 correlation of those CBGs with the location of telephone customers. Nor were CBGs
7 selected with any telephone design criteria in mind. Finally, cable plant was modeled as
8 a fixed (small) number of distribution cables of a fixed length, irrespective of the number
9 of households actually falling in the CBG.

10 By contrast, the clusters in HM 5.3 are determined using telephone company data on
11 where its customers are actually located. Specific counts of various kinds of lines are
12 associated with clusters using these data. Clusters are small. The number, length, and
13 size of the distribution cables are determined by the size of the cluster and the number of
14 lines being served. Strand normalization is used to ensure the total cable distance
15 meaningfully reflects the route miles of cable required to connect customer locations to
16 each other. Mr. Dippon may attempt to wave away the vast changes in modeling and
17 database techniques that have been incorporated into successive versions of the Model,
18 but those changes are no less real.

19 **Q. MR. DIPPON CLAIMS THAT THE VERIZON VZLOOP MODEL MORE**
20 **ACCURATELY REFLECTS RIGHTS OF WAY, ROAD LOCATIONS, AND**
21 **GEOGRAPHIC OBSTACLES THAN DOES HM 5.3 BECAUSE, FOR**
22 **INSTANCE, THE TERMINALS IT MODELS ARE TYPICALLY LOCATED ON**
23 **ROADS (DIPPON, PP. 23-24). IS THIS AN ACCURATE REFLECTION OF THE**

1 **SUPERIOR ASPECTS OF VZLOOP?**

2 A. No, it is not. I agree that existing terminal locations are likely to be located along roads
3 or in other rights-of-way. But ultimately, it is not the terminal locations that matter, it is
4 the route miles required to connect those locations to each other. In that respect, VzLoop
5 completely fails to model the road and rights-or-way routes, because it connects terminals
6 together using straight line segments. Such “beeline routing,” to use a pejorative term
7 formerly applied by ILECs to the HAI Model before it adopted more realistic routing
8 assumptions, is oblivious to geographic and other routing obstacles. Mr. Dippon may
9 fault the HM 5.3 model for failing to account for geographic obstacles (p. 27) and may
10 falsely claim AT&T/MCI admit to that failing (p. 22) – but the fact is HM 5.3 more
11 appropriately accounts for routing realities than does the VzLoop model.

12 **Q. MAP 1 ON P. 27 OF MR. DIPPON’S TESTIMONY SUGGESTS LARGE AREAS**
13 **OF RICHMOND BEACH ARE OMITTED FROM HM 5.3 DISTRIBUTION**
14 **AREAS. IS THIS AN ACCURATE REPRESENTATION?**

15 A. Either this is the most anomalous situations I have seen in any HM 5.3 database or Mr.
16 Dippon is not portraying the full set of HM 5.3 clusters that cover this area. Mr. Dippon
17 may fault the movement of customers within a cluster, but the TNS process does not omit
18 clusters covering such a populated area unless the customer data were missing in the first
19 place. We have not had sufficient time to fully investigate Mr. Dippon’s claims in the
20 short time since he filed his testimony, but subject to further check, I can only assume
21 Verizon omitted the data on customer addresses for this area, or that Mr. Dippon has not
22 drawn the complete picture. The kind of coverage shown in the maps on p. 81-82 of the
23 testimony is what one sees in the overwhelming majority of cases.

1 **Q. MR. DIPPON CLAIMS THAT “SINCE WORKING AROUND PHYSICAL**
2 **BOUNDARIES AND RIGHTS-OF-WAY IS COSTLY FOR REAL-WORLD**
3 **LOCAL EXCHANGE CARRIERS, IGNORING THEM CAUSES THE MODEL**
4 **TO PRODUCE SIGNIFICANTLY UNDERSTATED COST ESTIMATES” (P. 28).**
5 **DOES HE PRODUCE EVIDENCE THAT SHOWS HM 5.3 UNDERESTIMATES**
6 **COSTS?**

7 A. No. In fact, as I have previously noted, he shows that HM 5.3 produces more route miles,
8 not fewer route miles, than does VzLoop (Dippon, p. 63). This is true because HM 5.3
9 uses right angle routing to conservatively overestimate the route miles required between
10 two points. Therefore, while others may erroneously argue HM 5.3 underestimates costs
11 because of its price or other inputs, Mr. Dippon is certainly in no position to do so based
12 on this route mile comparison. And he is on shaky ground when he makes statements
13 like

14 “[L]ogic tells us that Verizon NW cannot place cables across highways or
15 through impenetrable natural or manmade structures, and it cannot ignore
16 rights-of-way. Nevertheless, this is what HM 5.3 assumes, thereby
17 rendering the Model itself and the cost estimates it produces useless
18 (Dippon, p. 38),

19 and

20 VzLoop, unlike HM 5.3, is able to model plant to customers using
21 appropriately sized distribution and feeder cables, and deploy the plant
22 along feasible network routes, such as roads (Dippon, p. 40).

23 **Q. DOES THE FACT THAT MR. DIPPON OSTENSIBLY USED A CBG-BASED**
24 **CLUSTERING MECHANISM, AS DESCRIBED AT PP. 40-42, AND GOT**
25 **ROUGHLY THE SAME RESULT AS HM 5.3 PRODUCES, PROVE THAT**
26 **THERE IS NO VALUE TO USING THE HM 5.3 CLUSTERS?**

1 A. No, not at all. There are a myriad of factors that make up the final result produced by the
2 Model, some of which increase costs and some of which decrease costs. The fact that a
3 particular study happens to turn out about the same statewide average result is, for all we
4 know, fortuitous. It would have been far more meaningful to show the results for a set of
5 wire centers, or for particular areas within that set of wire centers, to see if Mr. Dippon
6 had identified any specific cause why the results are invariant to the clustering
7 assumption.

8 **Q. MR. DIPPON FINDS IT A “FATAL” ERROR IN THE MODEL THAT AS THE**
9 **NUMBER OF CLUSTERS INCREASES, THE MODEL “ASSUMES AN**
10 **APPROXIMATELY EQUAL-SIZED DECREASE IN THE INVESTMENT PER**
11 **CLUSTER. FOR INSTANCE, IF THE NUMBER OF CLUSTERS IS DOUBLED,**
12 **THE INVESTMENT PER CLUSTER IS DECREASED BY APPROXIMATELY**
13 **50 PERCENT (DIPPON, P. 42-50). IS HE CORRECT THAT THIS IS A FATAL**
14 **FLAW OF THE MODEL?**

15 A. First of all, the Model “assumes” no such thing. Mr. Dippon is identifying a model
16 result, not an assumption the Model makes.

17 Is the relative invariance to cluster size a fatal error? No. Mr. Dippon has no *a priori*
18 basis for assuming this is an unreasonable result. In fact, when he made a similar claim
19 in the SBC-California proceeding, both Mr. Donovan and I explained why results might
20 not vary over a range of cluster sizes. As cluster size decreases, the increased investment
21 in feeder fiber and DLC equipment needed to penetrate more deeply into the network and
22 serve more customers is offset by a decrease in distribution investment because smaller
23 cables are less expensive. The CPUC Staff accepted this conclusion:

1 We find JA’s explanation on this point reasonable and we do not agree
2 with SBC-CA that Dippon’s “1800 run” proves HM 5.3 is flawed (CPUC
3 Proposed Decision, p. 79)

4 In that proceeding, Mr. Dippon’s analysis changed the maximum cluster size from 6,451
5 lines to 1,800 lines, which doubled the number of clusters. Here, he has made what may
6 appear to be a much more dramatic change, using whole CBGs as clusters. CBGs can be
7 very large in size, as I have noted previously. In fact, however, they are not large on the
8 average, because, for instance, CBGs in a downtown area may consist of only a few city
9 blocks. Mr. Dippon shows that the number of clusters increases from 1,019 to 2,517, or
10 about 2.5 times as many, and that this is comparable to the increase in the number of
11 clusters if the maximum cluster size is set to 900 lines. Therefore, it is not a dramatic
12 departure from the concept of clusters to equate them to CBGs instead of groups of
13 customer clusters.

14 In any event, the reclustering based on CBGs causes the loop cost to increase about 10%.
15 This is not a negligible change, although Mr. Dippon characterizes it as “merely” a 10%
16 change. And certainly the more than 25% change shown in Table 1 on p. 46⁶ when the
17 number of clusters is varied is quite significant. But whatever the changes, the key point
18 is that there is no *a priori* reason to expect any particular result, and Mr. Dippon presents
19 none. The only “fatal error” is that he had a pre-conceived notion of what the effect
20 would be, and that notion did not pan out in practice.

21 **Q. MR. DIPPON CLAIMS THE REASON THE RESULTS ARE INSENSITIVE TO**
22 **CLUSTER SIZE IS THAT NO MATTER WHAT SIZE CLUSTER IS ASSUMED,**

⁶ (\$10/\$7.87 is a 27% change, not a 15% change as Mr. Dippon claims).

1 **CUSTOMERS ARE SPREAD EVENLY THROUGHOUT THE CLUSTERS TO**
2 **WHICH THEY ARE ASSIGNED (DIPPON, PP. 52-53). IS THIS AN ACCURATE**
3 **CHARACTERIZATION?**

4 A. No. Once again, Mr. Dippon is ignoring the effect of the strand normalization factor.
5 While customers are initially distributed uniformly throughout a cluster by the Model, the
6 strand normalization process ensures that the actual distribution of customers is reflected
7 in the amount of cable utilized. There is certainly no reason to expect that as clusters are
8 sub-divided or combined, the strand normalization factors will continue to be the same or
9 have the same collective effect.

10 **Q. MR. DIPPON CLAIMS THAT “AFTER BEING SHOWN THE FIRST MAPS OF**
11 **HM 5.3’S MODELED OUTSIDE PLANT NETWORK, HOWEVER, AT&T/MCI**
12 **CHANGED THEIR APPROACH AND NOW CLAIM: ‘HM 5.3 IS NOT A**
13 **MODEL THAT BUILDS A NETWORK. IT’S A COSTING MODEL, AND IT**
14 **PRODUCES COSTS” (DIPPON, P. 59). IS THIS AN ACCURATE**
15 **REPRESENTATION OF A CHANGING ATTITUDE ON THE PART OF**
16 **AT&T/MCI AND THE HAI MODEL DEVELOPERS?**

17 A. No, it certainly is not. It has always been my position, and I believe the position of my
18 clients, that cost models estimate costs; they don’t design networks. If Mr. Dippon
19 believes to the contrary, he should produce engineering drawings showing Verizon
20 running cable in straight line segments from one distribution terminal to another. For that
21 matter, since HM 5.3 has accounted for geographic obstacles through the use of right
22 angle routing to provide a surplus of route miles, I think it would be very difficult for
23 Verizon to install cable in that pattern. Yet, from a costing point of view, the HM 5.3

1 treatment is more appropriate than the Verizon treatment because it is taking the cost of
2 avoiding obstacles into account whereas VzLoop does not.

3 **Q. DO YOU AGREE WITH MR. DIPPON THAT THE STRAND DISTANCE**
4 **PROVIDED BY TNS IS A FLOOR, RATHER THAN A CEILING, ON THE**
5 **AMOUNT OF CABLE THE MODEL SHOULD INSTALL (DIPPON, P. 62)?**

6 A. No, I do not. The strand distance is a right angle strand distance, which provides a
7 considerably greater amount of cable than a straight minimum spanning tree would
8 provide – as I have shown earlier, it produces on the average almost 30% more cable than
9 straight-line routing. Mr. Dippon has not identified any basis for believing this is still an
10 insufficient amount of route miles.

11 **Q. MR. DIPPON INDICATES THAT HM 5.3 PRODUCES MORE TOTAL ROUTE**
12 **MILES THAN DOES VZLOOP, BUT FEWER FEEDER MILES, THAT THIS IS**
13 **DUE TO THE FEWER NUMBER OF DISTRIBUTION AREAS IN HM 5.3, AND**
14 **THAT THIS IS A PROBLEM BECAUSE PER-FOOT FEEDER COSTS ARE**
15 **HIGHER (P. 63-65). DO YOU HAVE ANY COMMENTS ON THESE**
16 **OBSERVATIONS?**

17 A. Accepting his calculation of the route miles in the two models, the first point is correct. I
18 believe he has correctly identified the cause – the larger distribution areas in HM 5.3 – so
19 I agree with the second point. Concerning the third point however, Mr. Dippon is
20 forgetting his own analysis earlier in his testimony. There he showed that when clusters
21 are made smaller, the costs stay relatively fixed. This is because the feeder costs do
22 increase, but are offset by lower distribution costs. So modeling larger distribution areas
23 do not produce unreasonably low costs.

1 **Q. MR. DIPPON CLAIMS THE HAI MODEL VIOLATES ITS CONSTRAINT**
2 **THAT THE MAXIMUM ANALOG COPPER DISTANCE SHOULD NOT**
3 **EXCEED 18,000 FEET. IS HE RIGHT?**

4 A. He is referring to the same issue I discussed earlier in connection with Dr. Tardiff's
5 proposal to use post-normalization distances in deciding if a cluster needs to be split
6 and/or served by fiber feeder. As I stated there, I believe there is merit to Dr. Tardiff's
7 approach. However, I also showed that the effect was bounded by an increase of about
8 2.5% in the loop cost. So, Mr. Dippon appears to be right, but he has made no
9 assessment of the effect violating the constraint has on the loop results. The effect is
10 small.

11 **Q. MR. DIPPON DESCRIBES AS "ONE OF THE PRINCIPAL FAILINGS OF THE**
12 **MODEL" THE FACT THAT IT MODELS TO LOTS RATHER THAN TO**
13 **INDIVIDUAL LOCATIONS (P. 74). IS THIS A FAILING OF THE MODEL?**

14 A No. The lot count is used to obtain an initial estimate of the number of backbone and
15 branch cables required, and their length. If there were more lots, as Mr. Dippon suggests
16 there should be, the lot sizes would be smaller. According to the model's algorithms, this
17 would cause there to be a greater number of branch cables (and hence more route miles),
18 each of a smaller size because there are fewer lines served by each cable. That might or
19 might not cause the total costs to be higher. However, with strand normalization turned
20 on, the total route miles are normalized to the same strand distance in any case. Thus, the
21 effect of larger lot sizes would be to have the same number of route miles, but smaller
22 cables. Conversely, because we have reduced the number of lots, based on our
23 experience with the amount of space occupied by typical businesses and households in

1 multiple dwelling units, we get the same number of route miles (with normalization
2 turned on), but larger cable sizes. Thus, the lot reduction Mr. Dippon has identified
3 causes cable sizes to be larger, causing more cable investment. Mr. Dippon has erred in
4 his analysis of the effect of increasing the number of lots.

5 **Q. MR. DIPPON CLAIMS THAT THE CLUSTER DATABASE ERRS IN USING**
6 **THE CBG CHARACTERISTICS (LIKE LINE DENSITY, HOUSING**
7 **OCCUPANCY, AND GEOLOGICAL PARAMETERS) OF THE DOMINANT**
8 **CBG IN A GIVEN CLUSTER AS THE ATTRIBUTES FOR THAT CLUSTER,**
9 **RATHER THAN CALCULATING THE WEIGHTED AVERAGE CBG**
10 **CHARACTERISTICS ACROSS ALL THE CBGS SPANNED BY THAT**
11 **CLUSTER (DIPPON, P. 83-84). WOULD THIS CAUSE A SIGNIFICANT**
12 **DIFFERENCE IN THE MODEL’S RESULTS?**

13 A. In suggesting this effect, Mr. Dippon claims that “Although I raised this issue before in
14 the SBC-CA UNE proceeding, apparently AT&T/MCI did not deem it necessary to
15 adjust their Model” (p. 84). He also claims “Dr. Mercer stated that I did not ‘suggest
16 exactly how this should be done,’ and ‘the alleged error...actually results in lower loop
17 costs.’ There is apparently some miscommunication here. In the SBC California In that
18 proceeding, AT&T generated a new database that did exactly what Mr. Dippon
19 requested. I reported in my Rebuttal Testimony the result was that the loop cost dropped,
20 and provided the output that showed it.⁷ Since AT&T/MCI did not agree with the
21 philosophy behind this change, for the reasons I stated in my Rebuttal Testimony, it did

⁷ See Rebuttal Testimony of Dr. Robert A. Mercer, CPUC Docket CPUC Docket A.01-02-024 et al. March 12, 2003, paragraphs 17-19.

1 not implement the change on a going-forward basis. But there was nothing “alleged”
2 about the finding, and we were not uncooperative when Mr. Dippon made the request.

3 **IV. RESPONSE TO THE TESTIMONY OF FRANCIS J. MURPHY**

4 **Q. PLEASE SUMMARIZE THE NATURE OF MR. MURPHY’S TESTIMONY**

5 A. Like Dr. Tardiff’s testimony, Mr. Murphy’s attempts to cover the entire HM 5.3
6 waterfront -- in fact, there is a considerable overlap between the specific subjects dealt
7 with in the two testimonies. And like Dr. Tardiff’s testimony, many of Mr. Murphy’s
8 criticisms repeat old claims, many of which have arisen and been dealt with in other
9 jurisdictions; they pertain to inputs, not the model platform itself; they are not
10 constructive because they make criticisms without evidence or substance; they are
11 offered without an assessment of their impact on the results; and they demonstrate pre-
12 conceived notions of the way things should work that have no basis in fact.

13 **Q. MR. MURPHY CLAIMS “THE MODEL DISCARDS THE VAST MAJORITY OF**
14 **THE COSTS ATTRIBUTED TO THE ALL-FIBER NETWORK BASED ON AN**
15 **ERRONEOUS ASSUMPTION THAT CERTAIN UNES INCLUDED IN HM 5.3’S**
16 **SO-CALLED “HI-CAP” CATEGORY ARE NOT BEING PRICED IN THE**
17 **INSTANT PROCEEDING. THESE ERRORS ULTIMATELY LEAD TO THE**
18 **INAPPROPRIATE ELIMINATION OF MILLIONS OF DOLLARS OF**
19 **INVESTMENT (MURPHY, P. 14). IS IT AN ACCURATE**
20 **CHARACTERIZATION TO SAY THAT INVESTMENTS ARE BEING**
21 **DISCARDED?**

22 A. Not at all. A certain amount of structure and cable investment is associated with each of
23 the loop types present in the network, according to sharing rules described in Sections 8.8

1 and 9.4 of the HM 5.3 Model Description. Costs for the UNEs associated with certain
2 loop types – POTs and other narrowband loops, DS-1, DS-3 – are specifically calculated
3 by the Model in this proceeding. For those, the associated structure and cable costs are of
4 course included with the cost of other network components in arriving at the total cost of
5 that UNE. UNE Costs are not being developed for other types of loops – for instance
6 SONET OC-N loops. Those loops still have cable and structure costs associated with
7 them, but the costs are never used. At first hearing, this may sound like chicanery – the
8 investments are not discarded, they are just associated with UNEs for which costs are not
9 being calculated, and are thus set aside. But it is not chicanery at all. The point of the
10 sharing calculations is to get the right amount of cable and structure cost associated with
11 each loop type. The amount associated with, say, POTS loops is the same whether OC-N
12 UNE costs are presented in the Model output or not. It would not be appropriate to
13 increase or decrease the POTS assignment depending on what other UNEs were being
14 presented. Mr. Murphy may hold that all cable and structure costs should be assigned
15 only to UNEs at issue in this proceeding. But this flies in the face of the FCC guideline
16 for UNE models that held all demand should be reflected in sizing the network. It would
17 be incorrect to size the network for services like OC-N, but then assign all the network
18 costs to other UNEs.

19 **Q. MR. MURPHY CLAIMS THAT “CONTRARY TO A REAL-WORLD**
20 **NETWORK, HM 5.3 DOES NOT ACCOUNT FOR THE DEMAND PLACED ON**
21 **VERIZON NW’S IOF AND SWITCHES BY OTHER CARRIERS’ NETWORKS**
22 **(SUCH AS WIRELESS SERVICE PROVIDERS AND CLECS)” (MURPHY, PP.**
23 **15-16). IS THIS CORRECT?**

1 A. No, not as stated. First of all, other carriers require connections with Verizon to deliver
2 and receive traffic to/from Verizon. Interoffice trunks are provided to carry a user-
3 adjustable amount of traffic to other carriers. To the extent Mr. Murphy believes the
4 percentage is too low, we welcome whatever data he can provide on the correct amount.
5 Lacking such data, this becomes an idle complaint.

6 Second, in the SBC-California proceeding, it was claimed there are many more trunks
7 than just those required to carry the switched and dedicated traffic. It is not clear why
8 there would be a large amount of extra circuits, but let's suppose there is. With one
9 significant exception, it seems to me such circuits should ultimately show up in the loop
10 count, at the point where premises of the other carrier is connected to the Verizon wire
11 center. That connection should appear in the broadband loop inventory for the wire
12 center in question, and get treated as a broadband loop. To the extent a fraction of
13 broadband loops are assumed to have an interoffice component (this fraction is user-
14 adjustable), that fraction of loops to other carriers will also have an interoffice circuit.
15 This is appropriate, because a CLEC connected to, say, Wire Center A will often need to
16 connect to Wire Center B to deliver/receive traffic from that wire center, and will order
17 an interoffice circuit from A to B in addition to the loop. Again, Mr. Murphy may
18 believe the fraction of loops that have associated interoffice trunks is too low. If he has
19 credible data to that effect, this parameter can be changed.

20 The one exception is that a CLEC or other carrier may be collocated in Wire Center A,
21 yet still be ordering circuits to other wire centers above and beyond the number that the
22 HM 5.3 engineering of switched traffic determines is necessary. We might be missing
23 those circuits. They could readily be added – if Mr. Murphy reached the conclusion there

1 were extra IOF circuits by examining Verizon data, those data can be used to populate the
2 wire centers with additional traffic as well.

3 But lets assume all these mechanisms ultimately fail to identify and count all the circuits
4 present. Then the Model would calculate too little interoffice investment, which is
5 unfortunate. On the other hand, as I have discussed in Section II, Dr Tardiff's testimony
6 at p. 82 demonstrates a substantial economy of scale in the provision of interoffice traffic.
7 Total investment goes up as the number of circuits increases, but the investment per
8 circuit goes down. Thus, if there is an error in the number of IOF circuits the model is
9 counting, it lies in the direction of overestimating IOF UNE costs, not underestimating
10 them.

11 **Q. ACCORDING TO MR. MURPHY, THE TREATMENT OF LOCAL SWITCHING**
12 **IN HM 5.3 USES ILLOGICAL AND INCONSISTENT INPUTS AND**
13 **ASSUMPTIONS BECAUSE, FOR EXAMPLE, "INVESTMENTS ARE DERIVED**
14 **FROM A 1998 STUDY, BUT THEN [SWITCHES] ARE ASSUMED TO BE**
15 **EQUIPPED WITH OPTICAL SONET INTERFACING CAPABILITIES, WHICH**
16 **WOULD HAVE BEEN EXTREMELY RARE IN 1998" (MURPHY, P. 17). CAN**
17 **YOU COMMENT ON THIS ASSERTION?**

18 **A.** The Model is attempting to use forward-looking switch technology, hence the presence of
19 SONET interface capabilities assumed by the Model. To the extent Mr. Murphy is
20 correct that the switch prices we are using are outdated (presumably too high, since
21 switch prices have continued to drop in the intervening years), he is welcome to provide
22 the necessary data that shows the switch prices we should be using. Lacking such
23 evidence, however, the complaint is not constructive.

1 Q. MR. MURPHY CLAIMS THAT YOU AND MR. DONOVAN BOTH ADMITTED
2 DURING A WORKSHOP IN THE VERIZON-CALIFORNIA PROCEEDING
3 THAT “AN ENGINEER WOULD NOT DESIGN A NETWORK IN THE
4 MANNER MODELED BY HM 5.3.” (MURPHY, P. 26). IS THIS A CORRECT
5 CHARACTERIZATION OF WHAT YOU AND MR. DONOVAN ACTUALLY
6 SAID?

7 A. What Mr. Donovan and I actually said at the workshop is as follows (emphasis added):

8 MR. DONOVAN: I think that mischaracterizes what HM 5.3 is. HM 5.3
9 is not a model that builds a network. It's a costing model, and it produces
10 costs. And in that regard, yes, I have reviewed the costs for the outside-
11 plant portions of what that model does, and I'm familiar with that. It's not
12 out there trying work prints and trying to emulate what an engineer does.
13 It's a costing model.

14
15 MR. MERCER: Just so the record is clear on that, I've heard that played
16 back before: you're not really building a network. I mean, go back to the
17 discussion this morning where I said, If you add up all the vertical
18 distances of the minimum spanning tree, it doesn't matter at that point
19 whether I draw that cable off to the left or whether I leave it as a bunch of
20 vertical stacks; I still get the same amount of cable and same estimate
21 horizontally. You certainly would not think that's any kind of engineering
22 drawing. So when I now draw my cluster with a backbone cable right up
23 the middle of it, that's certainly not what the engineer is doing who's got to
24 put it in a real street, real corner. Nevertheless, because of the kind of
25 discussion we had this morning, you're getting the amount of cable right.
26 When we say we're not building a network, we mean it exactly and
27 narrowly. This is not an engineering plan for going in and putting in the
28 network. It's certainly a network that tries to get the total cost right, which
29 is all that it needs to do.

30 It is quite clear that Mr. Donovan and I were differentiating between a cost model
31 and an engineering plan, making the point that the goal of a cost model is to get
32 costs right, not to produce an engineering plan for installing the network. We
33 were certainly not saying an engineer would not design a network in the manner
34 modeled by HM 5.3. Thus, Mr. Murphy has twisted and mischaracterized our

1 words to support his implication that HM 5.3 uses design principles different than
2 those an outside plant engineer would utilize.

3 Let me also point out that no model, including VzLoop, provides engineering drawings
4 for deploying the network. If such a drawing was the output of VzLoop, it would show
5 cables running in straight lines through houses, fences, street lamps, and other obstacles
6 that happened to be in the way.

7 **Q. IN HIS DISCUSSION OF THE INVESTMENT EFFECTS OF STRUCTURE**
8 **SHARING STARTING AT P. 31, HAS MR. MURPHY SHOWN THE MODEL**
9 **MAKES ANY ERRORS?**

10 A. No. He makes no demonstration that the amount of structure sharing assumed by the
11 Model is incorrect. Nor does he point out that the amounts of all the forms of structure
12 sharing he discusses – sharing with other utilities, sharing between different components
13 of the Verizon network, and sharing between services on the same route – are all Model
14 inputs the user can adjust if there is a reasonable basis for doing so.

15 Worse, his discussion also demonstrates a lack of understanding of what sharing should
16 do to investment. According to Mr. Murphy,

17 “While the Model sponsors refer to the removed investments as ‘shared,’
18 the investment dollars computed in HM 5.3, and identified in these charts,
19 are not shifted from one part of the network to the other -- they are
20 removed entirely, and thus are never captured in any of the calculations
21 used to develop AT&T/MCI’s proposed UNE prices. (Murphy, p. 33)

22 Mr. Murphy is right, and that is the way investment should be impacted. If
23 through structure sharing – say, between distribution and feeder routes -- Verizon
24 is able to trench once instead of twice, or construct one pole instead of two, half

1 the investment is eliminated. A properly-crafted cost model like HM 5.3
2 recognizes this and removes the extraneous investment. It is unclear why Mr.
3 Murphy thinks the Model should put that investment somewhere else, or where he
4 thinks it should go.

5 The point is, all Mr. Murphy's colorful pictures have demonstrated is that
6 structure sharing provides Verizon with an opportunity to avoid investments it
7 would otherwise make, and that HM 5.3 properly recognizes these savings in
8 investments. They provide no basis for concluding either the amount of
9 sharing assumed by the Model or the way in which the model calculates the saved
10 investment is wrong.

11 **Q. STARTING AT P. 38 OF HIS TESTIMONY, MR. MURPHY PROVIDES A**
12 **LENGTHY DISCOURSE ON WHAT HE BELIEVES TO BE APPROPRIATE**
13 **OUTSIDE PLANT DESIGN PRACTICES AND HOW HM 5.3 FAILS TO MEET**
14 **THEM. DO YOU HAVE ANY COMMENTS ON MR. MURPHY'S**
15 **DISCUSSION?**

16 A. Mr. Fassett has commented on this discussion at some length. I will focus on some key
17 flaws I observe in Dr. Tardiff's discussion.

18 First, Murphy states that HM 5.3 errs in not providing sufficient capacity to meet the
19 ultimate demand expected in a distribution area (p. 40; see also p. 22). Providing
20 capacity for ultimate demand is not an appropriate goal for a properly-crafted model.

21 The SBC-CA Proposed Decision reaches a similar conclusion:

1 We agree with JA that based on established TELRIC rules, HM 5.3 should
2 not build to “ultimate demand.” In its own modeling for federal universal
3 service purposes, the FCC has stated that model inputs should reflect
4 current demand, which it defines to include a “reasonable amount of
5 excess capacity to accommodate short term growth.” The FCC has
6 explicitly rejected the notion of modeling based on “ultimate demand,”
7 because it is highly speculative. (CPUC Proposed Decision, p. 64-65,
8 citations omitted)

9 **Q. DOES THIS CONCLUDE YOUR REBUTTAL TESTIMONY?**

10 **A. Yes, it does.**
