Exhibit TJT-2: Academic Credentials and Professional Experience

1 **I. INTRODUCTION**

2 **Q. PLEASE STATE YOUR FULL NAME, EMPLOYER AND BUSINESS**

3 **ADDRESS.**

4 **A.** My name is Timothy J. Tardiff. I am a Vice President at National Economic Research
5 Associates (“NERA”), 1 Main Street, Cambridge, MA 02142.

6 **Q. PLEASE DESCRIBE YOUR EDUCATIONAL BACKGROUND AND WORK**
7 **EXPERIENCE.**

8
9
10 **A.** I received a B.S. degree from the California Institute of Technology in mathematics (with
11 honors) in 1971 and a Ph.D. in Social Science from the University of California, Irvine in
12 1974. From 1974 to 1979, I was a member of the faculty at the University of California,
13 Davis. I have specialized in telecommunications policy issues for over 20 years. My
14 research has included studies of the demand for telephone services, such as local
15 measured service and toll, analysis of the market potential for new telecommunications
16 products and services, assessment of the growing competition for telecommunications
17 services, and evaluation of regulatory frameworks consistent with growing competitive
18 trends.

19 I have extensive experience as a consultant and expert witness in regulatory
20 proceedings. My recent experience includes in-depth evaluations of the HAI Model
21 (Releases 5.2a and 5.3) and the Federal Communications Commission’s (“FCC’s”)
22 universal service cost proxy model, the “Synthesis Model.” I have also testified in
23 state proceedings and arbitrations (pursuant to the Telecommunications Act of 1996) on
24 local network unbundling, universal service funding, and most recently implementing the
25 FCC’s Triennial Review Order (“TRO”), in Alabama, Alaska, Arkansas, California, the

1 District of Columbia, Indiana, Kansas, Kentucky, Maine, Maryland, Massachusetts,
2 Missouri, New Hampshire, New Jersey, New York, North Carolina, Ohio, Oklahoma,
3 Pennsylvania, Rhode Island, South Carolina, Texas, Vermont, and Virginia. A copy of
4 my curriculum vitae is attached hereto as Exhibit TJJ -1.

5 **Q. PLEASE SUMMARIZE YOUR TESTIMONY.**

6 **A.** AT&T Communications of the Pacific Northwest, Inc. ("AT&T") and WorldCom, Inc. (d/b/a
7 "MCI") (collectively "AT&T/MCI") have submitted the HAI Model, Release 5.3 ("HM 5.3
8 Revised" or "Model") for the purpose of calculating Verizon Northwest Inc.'s ("Verizon
9 NW") forward-looking costs of providing unbundled network elements ("UNEs") in
10 Washington. I have reviewed the supporting testimonies of Dr. Mercer, Mr. Donovan,
11 and Dr. Bryant filed on behalf of AT&T/MCI,¹ and have analyzed HM 5.3 Revised's
12 calculations and outputs. Based on this evaluation, as well as the Reply Declarations of
13 Messrs. Dippon, Murphy, and Richter, I conclude that HM 5.3 Revised produces UNE
14 cost estimates that are significantly lower than the economic costs Verizon NW incurs
15 when it provides UNEs to competitive local exchange carriers ("CLECs").

16 For a cost model to produce accurate estimates of the economic costs a carrier
17 incurs in offering UNEs, it must accurately represent both the *quantities* and *types* of
18 network facilities (e.g., the number of poles, the length of 25-pair buried cables, etc.) and
19 the *prices* a carrier pays for these facilities. In addition to the investments associated
20 with network facilities, a cost model must also incorporate accurate estimates of the
21 costs necessary to operate the network on a going-forward basis. Modeling reasonable
22 quantities of network facilities requires a realistic depiction of the efficiencies available to

Formatted: Right

1 a carrier in designing a network and purchasing facilities to be used therein. For
2 example, the cost model must produce feeder and distribution routes of sufficient
3 lengths, must have adequate and realistic amounts of cable and support facilities, must
4 model enough capacity to enable efficient operation, and must depict prices for assets
5 (such as switches) that the carrier would expect to pay. A careful evaluation of HM 5.3
6 Revised shows that it does not provide reasonable estimates of these prices and
7 quantities. In particular:

Deleted: HM 5.3

- 8 • As described by Mr. Dippon, HM 5.3 Revised's cluster input data,
9 which are intended to approximate the incumbent local exchange
10 carrier's ("ILEC") distribution areas, do not adequately represent
11 the routes necessary to connect customer locations to the proper
12 types and amounts of loop facilities along those routes. In
13 addition, as Mr. Murphy describes, the engineering criteria used
14 to produce HM 5.3 Revised's clusters do not comport with how
15 an engineer would design outside plant.²
- 16 • HM 5.3 Revised does not provide the requisite amounts of
17 capacity necessary to operate a network efficiently.
- 18 • To a large extent -- and particularly for the amount of labor
19 required to engineer and install telephone plant -- the prices
20 recommended by Mr. Donovan for purchasing and installing
21 network facilities are based on the unsubstantiated, subjective
22 judgment of AT&T/MCI's consultants and/or dated and
23 unverifiable sources that are not Washington-specific. As Mr.
24 Murphy describes in detail,³ these recommended prices fail to

Deleted: HM 5.3

Deleted: HM 5.3

Deleted: HM 5.3

(...continued)

¹ Mr. Donovan's testimony was also filed on behalf of XO Washington, Inc.

² In particular, the Reply Declarations of Messrs. Dippon and Murphy take issue with the statement: "Thus, the clusters developed pursuant to this process are likely to be the most closely representative of actual telephone distribution areas as determined by outside plant engineers." Before the Washington Utilities and Transportation Commission, Docket UT-023003, *Supplemental Direct Testimony of Dr. Robert A. Mercer on behalf of AT&T Communications of the Pacific Northwest, Inc.* (Jan. 23, 2003) at Exhibit RAM-4 (HAI Model Release 5.3 Model Description ("Model Description")) at p. 35 ("Mercer Supplemental Direct Testimony"). Unless otherwise specified, my analyses are based on the version of HM 5.3 Revised filed by AT&T Communications of the Pacific Northwest, Inc. ("AT&T") on June 4, 2004.

Formatted: Right

1 comport with what Verizon NW expects to pay on a going-
2 forward basis for network facilities and, in some cases, differ in
3 implausible ways from what Mr. Donovan recommended in
4 previous proceedings involving prior versions of the HAI Model.⁴

- 5 • HM 5.3 Revised does not properly represent the economic
6 conditions a carrier providing UNEs would encounter. In addition
7 to providing insufficient levels of capacity, the cost of capital and
8 depreciation inputs used by Dr. Mercer are not consistent with
9 the risks that a competitive provider of UNEs would face,
10 especially one that was subject to regulatory-determined
11 reductions in UNE prices several times over the economic lives
12 of network assets.⁵ In addition, HM 5.3 Revised's switch cost
13 algorithm assumes, unrealistically, that an efficient carrier would
14 instantaneously purchase all new switches at deep discounts. In
15 the real world, however, carriers purchase large portions of their
16 switching equipment at higher prices as they equip different
17 locations at different points in time.

Deleted: HM 5.3

Deleted: HM 5.3

18 **Q. HAVE AT&T/MCI ENDEAVORED TO TEST OR VALIDATE THE COST**

19 **ESTIMATES PRODUCED BY HM 5.3 REVISED?**

Deleted: HM 5.3

Deleted: HM 5.3

- 20 **A.** No. AT&T/MCI have not tested, let alone verified, whether HM 5.3 Revised produces
21 valid and accurate estimates of network investments, operating costs, and UNE costs.⁶
22 Because telecommunications networks and the cost models that depict them are
23 incredibly complex, quantitative tests of model outcomes are essential to determine
24 whether the cost model is functioning properly and producing costs that an actual carrier
25 offering UNEs in the real world can reasonably expect to achieve. Such quantitative

⁴ For example, the prices for installed copper and fiber cable are considerably lower than the prices used in previous versions of the HAI Model, primarily due to HM 5.3 Revised's unreasonable reductions for engineering and installation labor costs.

Deleted: HM 5.3

⁵ Before the Federal Communications Commission, CC Docket Nos. 01-338, 96-98, 98-147, *Report and Order on Remand and Further Notice of Proposed Rulemaking* (rel. Aug. 21, 2003) at ¶¶ 680 and 689 ("TRO"); Before the Federal Communications Commission, CC Docket No. 03-173, *Notice of Proposed Rulemaking* (rel. Sept. 15, 2003) at ¶¶ 83-84 ("TELRIC NPRM").

⁶ See, e.g., Before the Washington Utilities and Transportation Commission, Docket No. UT-023003, *Joint Responses of AT&T & MCI to Verizon's First Set of Data Requests* (July 24, 2003) at Response Nos. 1-7 and 1- (continued...)

1 tests should determine, for example, whether the investment levels (e.g., on a per-line
2 basis) produced by the Model approximate the investment levels that carriers actually
3 have achieved.

4 An additional validation test is whether successive releases of the HAI Model
5 (typically sponsored by AT&T/MCI's witnesses in this proceeding) are consistent with
6 reasonable trends in the industry. For example, in arguments before the United States
7 Supreme Court and, most recently, in the FCC's ongoing total element long run
8 incremental cost ("TELRIC") investigation, CLECs argued that the FCC's TELRIC rule
9 could produce loop costs that are *higher* than historical levels because only the
10 computer-based network components (e.g., switching) were subject to large productivity
11 gains.⁷ Despite these prior unqualified observations that loop costs should not be
12 expected to decline, HM 5.3 Revised produces the opposite outcome – AT&T/MCI's
13 proposed loops costs are substantially lower than those produced by previous versions
14 of the HAI Model.

Deleted: HM 5.3

15 In fact, HM 5.3 Revised falls short on both validation tests:

Deleted: HM 5.3

(...continued)

20; Before the Washington Utilities and Transportation Commission, Docket No. UT-023003, *Joint Responses of AT&T & MCI to Verizon's Sixth Set of Data Requests* (Aug. 5, 2003) at Response Nos. 6-5 and 6-33.

⁷ "Although the computer-based elements of the network (such as the switches) may be characterized by declining costs, *other elements (such as the loop plant) are not declining; for many elements costs are rising.*" *WorldCom, Inc. v. Verizon Communications, Inc.*, Reply Brief for Petitioners WorldCom, Inc., the Association for Local Telecommunications Services, and Competitive Telecommunications Association, No. 00-555 (July 23, 2001) at p. 6 (emphasis added). Indeed, during the October 10, 2001 argument before the U.S. Supreme Court, Donald Verrilli, counsel for MCI, correctly explained that loop costs have not come down over time. *Verizon Communications, Inc. v. Federal Communications Commission*, No. 00-511, et al., Oral Argument before the Supreme Court (Oct. 10, 2001) at pp. 74-75 ("Supreme Court Argument"). In fact, the U.S. Supreme Court's decision upholding TELRIC made the same observation with respect to loop costs. See *Verizon Communications Inc. v. Federal Communications Commission*, 122 S. Ct. 1646 (May 13, 2002). AT&T/MCI have repeated these arguments in the ongoing TELRIC NPRM. See, e.g., Before the Federal Communications Commission, CC Docket Nos. 01-338, 96-98, 98-147, *Comments of AT&T Corp.* (Dec. 16, 2003) at pp. 99-100.

Formatted: Right

1 • HM 5.3 Revised produces investment levels that are *less than 30*
2 *percent* of the cost of reproducing Verizon NW's network.⁸ While
3 some reduction might be expected for some facilities, such as
4 switching, HM 5.3 Revised makes large across-the-board
5 reductions. In fact, the reduction for cable and wire facilities
6 (copper cable, fiber cable, and their support structures) is even
7 more drastic. Similar reductions occur for expenses. For
8 example, HM 5.3 Revised assumes, unrealistically, that an
9 "efficient carrier" serving Verizon NW's customers could maintain
10 the same number of switch locations, serving the same customer
11 volumes, and using the same switch technology (i.e., digital), for
12 *only 56 percent* of the costs incurred by Verizon NW in 2002.

Deleted: HM 5.3

Deleted: HM 5.3

Deleted: HM 5.3

13 • Contrary to MCI's statements to the United States Supreme
14 Court,⁹ loop costs have declined substantially over successive
15 versions of the HAI Model presented to the Washington Utilities
16 and Transportation Commission ("Commission"). In 1997,
17 Version 3.1 produced a loop cost of \$14.58;¹⁰ and in this
18 Commission's 1998 universal service proceeding, HM 5.0a
19 produced a loop cost of \$12.62.¹¹ This year, AT&T/MCI
20 advocate a loop cost of \$8.50, which is less than 43 percent of
21 this Commission's current rate of \$20.¹²

Deleted: 7.64

Deleted: 0

22 Such drastic across-the-board reductions are unwarranted and cast serious doubt

Deleted: HM 5.3

23 on the reliability of the UNE cost estimates produced by HM 5.3 Revised.

⁸ While a reproduction cost is not exactly the same as a forward-looking economic cost, particularly when technologies are changing rapidly, it provides a reasonable benchmark, especially when: (1) the actual and forward-looking facilities are the same (e.g., digital switching); and (2) the components of the network are not subject to rapid technological advance.

⁹ See note 7 *supra*.

¹⁰ Before the Washington Utilities and Transportation Commission, Docket Nos. 960369, -370, -371, *Supplemental Direct Testimony of John C. Klick* (February 21, 1997) (sponsoring Hatfield Model Release 3.1).

¹¹ Before the Washington Utilities and Transportation Commission, Docket No. 980311(a), *Direct Testimony of Robert Mercer on behalf of AT&T & MCI* (June 15, 1998) (sponsoring HAI Model, Release 5.0a).

¹² Before the Washington Utilities and Transportation Commission, Docket Nos. 960369-, -370, -371, *Eighth Supplemental Order Interim Order Establishing Costs for Determining Prices in Phase II; and Notice of Prehearing Conference* (April 16, 1998) at ¶ 270 ("1998 Eighth Supp. Order"). In fact, the line-weighted average of the current deaveraged loop rates is over \$24.00, implying that AT&T/MCI's proposed loop rate is a little more than one-third of the existing rate.

Deleted: less than

1 II. ECONOMIC ISSUES

2 Q. DO YOU AGREE WITH DR. MERCER'S CLAIM THAT HM 5.3 REVISED IS THE MOST
3 APPROPRIATE MODEL FOR ESTIMATING VERIZON NW'S FORWARD-LOOKING
4 COSTS OF PROVIDING UNES?

Deleted: HM 5.3

5 A. No. Dr. Mercer claims, incorrectly, that HM 5.3 Revised is the most appropriate model
6 for determining Verizon NW's forward-looking costs (and alleges this is consistent with
7 FCC's TELRIC rules).¹³ In order to assess this claim, it is essential to understand the
8 FCC's *intent* in establishing TELRIC. The FCC's TELRIC methodology is intended to
9 identify an incumbent carrier's actual forward-looking costs,¹⁴ and thus replicate, "to the
10 extent possible, the conditions of a competitive market."¹⁵ Indeed, in its last brief to the
11 United States Supreme Court (in the case that upheld its TELRIC rules), the FCC
12 explained that the costs of the ILEC itself were the focus of the TELRIC rules:

Deleted: HM 5.3

13 The costs measured by TELRIC are nonetheless those of the
14 incumbent itself. Those costs are based, moreover, on actual prices
15 of equipment that is commercially available today – equipment that
16 carriers are already using to upgrade and expand their networks.¹⁶

¹³ Mercer Supplemental Direct Testimony at pp. 5, 9-10. In addition, Dr. Bryant made similar claims for the version of HM 5.3 that AT&T/MCI submitted last year. Before the Washington Utilities and Transportation Commission, Docket No. UT-023003, *Direct Testimony of Dr. Mark T. Bryant on behalf of AT&T Communications of the Pacific Northwest, Inc. and WorldCom, Inc.* (June 26, 2003) at pp. 1-2 ("Bryant Direct").

¹⁴ The FCC's TELRIC methodology is intended to produce "costs that incumbents actually expect to incur in making elements available to new entrants." In the Matter of Implementation of the Local Competition Provisions in the Telecommunications Act of 1996, CC Docket No. 96-98, *First Report and Order*, FCC 96-325 (rel. Aug. 8, 1996) ("First Report and Order") at ¶ 685.

¹⁵ First Report and Order at ¶ 679.

¹⁶ *Verizon Communications, Inc. v. Federal Communications Commission*, No. 00-511, et al., Reply Brief for Petitioners Federal Communications Commission and the United States (July 2001) at p. 6 (See, e.g., *AT&T v. FCC*, 220 F.3d 607, 617 (D.C. Cir. 2000) (state commission, in setting TELRIC price for switching element, looked to prices of switches recently purchased by incumbent)).

Formatted: Right

Deleted: HM 5.3

1 HM 5.3 Revised does not adhere to this TELRIC standard because it does not accurately
2 estimate the total costs that Verizon NW, or any efficient carrier, can “actually expect to
3 incur,”¹⁷ even under forward-looking conditions.

4 The test of whether any particular model is consistent with TELRIC principles
5 centers on whether the cost model produces the quantities and types of equipment that
6 would be observed in a competitive market and whether (as the FCC explained) the
7 prices for the equipment approximate what carriers pay today. As explained by Mr.
8 Murphy,¹⁸ many of the cost inputs recommended by AT&T/MCI, especially for installation
9 labor, are based solely on the judgments of Mr. Donovan and his engineering team, the
10 majority of which were formed many years ago and are unsupported by any empirical
11 evidence.

12 AT&T/MCI interpret TELRIC to require ubiquitous replacement; their theoretical
13 construct assumes that a new entrant would deploy facilities to “efficiently” accommodate
14 a known and fixed level of demand, more or less precisely located. Although, as Mr.
15 Dippon demonstrates, their Model fails to locate customers with any precision.¹⁹ In
16 building a network under such favorable circumstances, AT&T/MCI assume that the
17 hypothetical new entrant will enjoy the following advantages: (1) facilities are directly
18 routed to customer locations, even though a carrier that builds sequentially as demand
19 materializes or changes over time might have less direct routes; (2) lower levels of
20 capacity are needed because demand is known with a high degree of certainty; (3) more

¹⁷ First Report and Order at ¶ 685.

¹⁸ Murphy Reply Testimony at Section VI.

¹⁹ Dippon Reply Testimony at Section V.

1 opportunities exist to share structures (e.g., utility poles and buried cable) with other
2 carriers; (4) there are economies of scale related to mass deployment of facilities, such
3 as telephone poles, because work crews can be deployed more efficiently than those of
4 actual telephone companies;²⁰ (5) much greater initial discounts are available because
5 all equipment is purchased at the same time to serve the entirety of demand; and (6) the
6 latest vintages of technology can be deployed ubiquitously throughout the network, even
7 in cases where compatibility among various network components would make such
8 deployment uneconomic for any real firm. As discussed more fully below, such an
9 aggressive interpretation of TELRIC is extremely unrealistic and inconsistent with the
10 FCC's pronouncements on the matter.

11 **Q. PLEASE EXPLAIN HOW AT&T/MCI'S INTERPRETATION OF TELRIC IS**
12 **INCONSISTENT WITH THE FCC'S PRONOUNCEMENTS ON THE MATTER.**
13

14 **A.** The FCC does not require such an aggressive interpretation of TELRIC;²¹ indeed, such
15 an interpretation could never produce accurate UNE cost estimates. Assuming a level of
16 "efficiency" that no real carrier can achieve does not approximate competitive conditions,
17 but rather only serves to produce uneconomically low cost estimates. In particular, the
18 hypothetical routes modeled and facilities deployed by HM 5.3 Revised do not take into
19 account real-world obstacles such as rivers and roads -- an erroneous modeling
20 technique that unjustifiably decreases costs.
21

Deleted: HM 5.3

²⁰ Before the Federal Communications Commission, WC Docket No. 03-173, *Declaration of Michael D. Pelcovits on behalf of MCI* (Dec. 16, 2003) at p. 29.

²¹ Most recently, the FCC tentatively concluded that TELRIC rules should more closely account for real-world attributes of an incumbent's network. TELRIC NPRM at ¶ 52. Interestingly, the FCC's Wireline Competition Bureau's opinion in the Virginia arbitration found Verizon's models, which are informed by characteristics of the existing network, to be consistent with forward-looking cost principles. See e.g., Before the Federal
(continued...)

Formatted: Right

Deleted: HM 5.3

1 Moreover, HM 5.3 Revised's modeling of lower amounts of capacity (or higher fill
2 factors) than Verizon NW maintains in its network is similarly flawed. The FCC has
3 rejected claims that lower amounts of capacity are necessarily consistent with TELRIC
4 principles,²² perhaps in recognition of the fact that, because Verizon NW's interstate
5 services have been subject to price-cap regulation for well over 10 years and the bulk of
6 its intrastate services are subject to price regulations throughout its multi-state territory, it
7 has strong incentives to employ economically efficient amounts of capacity.²³
8 Accordingly, current levels of capacity are assumed to be reasonable, as evidenced by
9 the fact that these levels have remained stable over time.

Deleted: HM 5.3

10 Q. **DOES HM 5.3 REVISED'S NETWORK DESIGN INCLUDE ALL RELEVANT**
11 **ECONOMIC COSTS?**

Deleted: HM 5.3

12 A. No. HM 5.3 Revised specifically excludes, *by design*, the costs incurred in operating a
13 dynamic network (i.e., one with sufficient capacity) on a going-forward basis. A network
14 with insufficient capacity to accommodate churn, irregularly distributed demand,
15 fluctuations in demand over time, and overall growth in demand, cannot serve a carrier's
16 customers without an unacceptable risk of service disruption or a high probability that
17 customer demand for service would go unsatisfied. A network cannot be said to "serve"
18 existing demand if it is not flexible enough to accommodate changes and
19 rearrangements in that demand. As Mr. Murphy explains, engineering guidelines for

(...continued)

Communications Commission, CC Docket Nos. 00-218, -249, 251, *Memorandum Opinion and Order* (rel. Aug. 29, 2003) at ¶ 49 ("Virginia Arbitration Order").

²² Joint Application by BellSouth Corporation, BellSouth Telecommunications, Inc., and BellSouth Long Distance, Inc. for Provision of In-Region, InterLATA Services In Georgia and Louisiana, CC Docket No. 02-35, *Memorandum Opinion and Order* (May 15, 2002) at ¶ 70 ("BellSouth Order").

1 local exchange networks are designed to cope with three undeniable facts: (1) demand
2 changes over time; (2) demand is uncertain, both as to place and time (i.e., it cannot be
3 determined in advance *which* customers will move, when they will move, or how many
4 lines they will want); and (3) technological change and changing market conditions
5 require periodic upgrades to software and hardware.²⁴ In this environment, it is not
6 efficient for a telecommunications carrier to install only the equipment it will need at a
7 single point in time. Rather, an efficient carrier will install plant that includes enough
8 capacity so that the utilization of that capacity (e.g., “fill factors”) are adequate to: (1)
9 accommodate movement of existing customers and their services, (2) meet short-run
10 demand growth (e.g., two to three years for new switches), and (3) implement growth
11 jobs and upgrades over the life of the plant. Therefore, to minimize costs, efficient firms
12 continually adjust their factors of production to augment and replace facilities. The long-
13 run costs of all real-world networks reflect this fundamentally dynamic optimization
14 process.

15 Economists recognize that the textbook long-run case -- i.e., a period long enough
16 to allow a firm to reach its optimum scale of operation -- is a hypothetically limiting one,
17 and does not reflect the conditions pursuant to which real-world telecommunications
18 firms operate. Even new entrants are constrained by current conditions, including the
19 inherent uncertainty in the location and amount of customer demand over time. No firm
20 has sufficient knowledge about current and future technologies to determine, in advance

(...continued)

²³ The FCC’s TELRIC NPRM explored this proposition. See TELRIC NPRM at ¶ 58.

²⁴ Murphy Reply Testimony at Section V.

1 of making any investment decisions and with perfect certainty, what its global cost-
2 minimizing scale of operations might be. Further, technologies are *not* perfectly
3 foreseeable. Therefore, a real-world firm necessarily makes investment decisions
4 without perfect knowledge of the future of technology or demand, but with the
5 expectation that demand will grow and shift over time and that facilities will be relieved
6 and replaced. The uncertainties of demand in the real world cannot be eliminated, no
7 matter how “forward-looking” or “long-run” the approach.²⁵ HM 5.3 Revised, with its
8 static view of the network, and its idealized notion of what is required to provide service -
9 - particularly as reflected in its utilization and certain equipment price inputs -- assumes
10 an unrealistic level of efficiency that is in no way required by TELRIC.

Deleted: HM 5.3

11 **Q. PLEASE DESCRIBE SOME OF THE PROBLEMS ASSOCIATED WITH HM**
12 **5.3’S APPROACH TO MODELING A FORWARD-LOOKING NETWORK.**

13 **A.** One of the problems with HM 5.3 Revised’s modeling approach is its removal of a
14 substantial amount of the current, and very real, costs needed to accommodate growth
15 and respond to changes in demand. HM 5.3 Revised implicitly assumes that an ILEC
16 would instantly size its entire outside plant network based on the amount and location of
17 current demand, and thereby realize unrealistic economies that can only be obtained

Deleted: HM 5.3

Deleted: HM 5.3

²⁵ This issue is addressed by the application of “real options” theory to telecommunications costing. Professor William Baumol, a prominent economist and frequent consultant to AT&T, described this theory as follows:

[O]ne can characterize the pertinent part of the new analysis as follows. It tells us that investment decisions typically have a cost component that has usually been overlooked, so that the total costs of such decisions (and, hence, their appropriate price) is normally underestimated. The overlooked cost component is the narrowing of future choices that a current investment commitment entails. By making such a commitment, the decision makers forego some of their future options. The decisions preclude choices the decision makers *may* prefer to change as the passage of time increases the information available to them. But such changes are no longer open to them because of their investment commitment.

William J. Baumol, “Option Value Analysis and Telephone Access Charges,” in James Alleman and Eli Noam, eds., *The New Investment Theory of Real Options and its Implications for Telecommunications Economics*, Boston: Kluwer (1999).

1 when total demand is served by ideally-sized facilities purchased at maximum volume
2 discounts. This assumption is counterfactual: real-world firms must grow to meet
3 demand as it materializes over time (growth), and must be structured to respond to shifts
4 in demand at particular locations (churn). Firms -- including efficient ILECs, as well as
5 new entrants -- add capacity over time, taking into account the trade-off between the
6 lower per unit costs of bigger modules (e.g., larger switches and larger cable sizes), the
7 costs incurred to add capacity (a particularly significant factor for outside plant facilities),
8 and the costs of carrying unused capacity. The markets for critical inputs (e.g., switches,
9 outside plant facilities, and the labor to install them) reflect these fundamental facts.
10 Indeed, carried to its logical conclusion, insistence on the proposition that TELRIC costs
11 should assume that the network could be built instantaneously would require much
12 higher prices for such inputs to reflect the supply constraints that such a scenario would
13 necessarily impose.

14 With regard to switch prices, approximating what a carrier pays today must
15 account for factors such as: (1) economic choices among multiple vendors, and (2) the
16 relative mix of new and add-on equipment that the carrier expects to incur. HM 5.3
17 Revised's assumption that Verizon NW's switches will be purchased at deeply
18 discounted new switch prices fails to reflect Verizon NW's forward-looking costs. In the
19 competitive market that TELRIC is designed to emulate, new entrants (or incumbents for
20 that matter) would not purchase only new switches to serve their entire volume of lines

1 and usage at a single point in time.²⁶ Rather, competitive carriers would purchase a mix
2 of new and add-on modules.²⁷

3 **Q. ARE ~~HM 5.3 REVISED'S~~ COST OF CAPITAL AND DEPRECIATION ASSUMPTIONS**
4 **TELRIC-COMPLIANT?**

5 **A.** No. Economic depreciation and cost of capital rates are intended to approximate how a
6 firm would recover its investments given the competitive conditions anticipated (or
7 assumed) by a given cost model. AT&T/MCI's aggressive interpretation of TELRIC
8 implicitly assumes extremely competitive conditions that are fundamentally at odds with
9 how AT&T/MCI assume Verizon NW would recover and earn a return on its investment
10 over time. In particular, they assume, unrealistically, the existence of a competitive
11 environment wherein: (1) a large proportion of a firm's costs are for assets with long
12 lives; (2) some of these assets are subject to technological advancement (and hence
13 declining prices over time); (3) the competitive environment provides no guarantee that
14 the expected demand will be sustained over the anticipated economic life of the assets;
15 and (4) UNE prices will be provided at regulated prices indefinitely.²⁸ In stark contrast,

²⁶ Even if there were a firm that would purchase only new switches (which is unlikely), it would be highly improbable for vendors to offer the same new switch discounts, because there would not be an opportunity to charge higher prices on a sufficiently large volume of add-on lines to make up for the low new equipment prices. For example, if the add-on price were twice the new line price, and a mix of 50 percent new lines and 50 percent add-ons permitted a vendor to recover its cost, a 90/10 mix would not allow the vendor to recover its costs.

²⁷ More generally, Verizon NW's equipment prices reflect the specific terms offered by equipment vendors, *including the expectations by both parties about the relative mix of new and add-on equipment*. It is thus incorrect to mix and match Professor Baumol's long run (where contacts and commitments have expired) with the extreme short run of a particular contract (see First Report and Order at n.1682). It is also interesting to observe that the FCC's First Report and Order does not even remotely mention price concerns when explaining why a long-run study is desirable. See First Report and Order, *passim*. The FCC noted, "The 'long run' approach ensures that rates recover not only the operating costs in the very short run, but also fixed investment costs that, while not variable in the short term, are necessary inputs directly attributable to providing the element." First Report and Order at ¶692.

²⁸ AT&T/MCI have essentially ignored the FCC's directive to assume the existence of facilities-based competition in estimating depreciation and cost of capital rates. Instead, they continue to insist that there will be little to no
(continued...)

Deleted: HM 5.3

1 the Model then treats recovery of investment essentially the same as a *guaranteed* loan
2 for the duration of the economic life -- i.e., HM 5.3 Revised determines the constant
3 payment Verizon NW would need to collect each and every period in order to depreciate
4 its assets and earn an economic return on the assets' remaining value. This
5 misalignment of competitive assumptions with the assumed pattern of cost recovery
6 necessarily means that Verizon NW could *not* recover the costs of its investments in a
7 way analogous to a long-term loan.

8 **Q. WHAT IMPACT WOULD THE EXTREMELY COMPETITIVE CONDITIONS IMPLIED**
9 **BY AT&T/MCI'S AGGRESSIVE INTERPRETATION OF TELRIC HAVE ON THE**
10 **SELECTION OF ACCURATE VALUES FOR DEPRECIATION AND COST OF**
11 **CAPITAL?**

12 **A.** The Model's over-arching assumption -- that an "efficient firm" is one that
13 instantaneously sizes its network to "optimally" accommodate current demand at current
14 locations -- necessarily implies significantly shorter depreciation lives and a significantly
15 higher cost of capital than are typically experienced in regulated industries. AT&T/MCI
16 are able to achieve unreasonably low UNE cost estimates, in part, by failing to account
17 for the shorter depreciation lives and higher cost of capital necessitated by HM 5.3
18 Revised's assumptions.

Deleted: HM 5.3

competition for network elements, and, at the same time, justify the use of the hyper-competitive assumptions regarding network equipment discussed above on the basis of a "perfect contestability" assumption. See e.g., Before the Federal Communications Commission, CC Docket No. 03-173, *Declaration of Robert D. Willig* (Dec. 16, 2003) at pp. 52-59. The fundamental flaw with this line of reasoning is that the assumptions underlying "perfect contestability" (i.e., that entry and exit are costless) are at odds with the characteristics of telecommunications networks, (i.e., a cost structure with a high representation of long-lived capital assets, many
(continued...)

Formatted: Right

1 In addition, the Model assumes that the optimally -configured and perfectly -sized
2 network that is built today will again be instantaneously replaced every few years when
3 prices are recalculated based upon another all-new network. Again, assumptions such
4 as this require shorter depreciation lives and a higher cost of capital -- in the real-world,
5 carriers investing in assets with long lives are substantially constrained by such
6 investments because long-term investments are likely to become "stranded" if they are
7 assumed to be replaced every few years by an all-new, optimally -configured network
8 using the most recent technologies available. This need for shorter depreciation lives
9 and a higher cost of capital is true not only for assets that experience relatively high rates
10 of technological progress (such as switches),²⁹ but also for assets such as outside plant
11 facilities, because HM 5.3 Revised's assumptions would render the ILEC's formerly
12 "optimal" configuration inefficient.³⁰

of which are subject to change), as well as the inherent uncertainty of maintaining adequate demand levels over the lives of network assets.

²⁹ See, e.g., Alfred E. Kahn, *Letting Go: Deregulating the Process of Deregulation*, East Lansing: Michigan State University (1998) at pp. 91-92 and Jerry A. Hausman, "Valuing the Effect of Regulation on New Services in Telecommunications," Brookings (1997). Professor Hausman estimates that annual charge factors, based on traditional regulatory depreciation and cost-of-capital, can be too low by a factor of 2 to 3.

³⁰ For example, suppose the luxury of starting from scratch allowed a hypothetical entrant to serve current lines with 20 percent fewer telephone poles than an ILEC. If this were a realistic possibility (which it is not), then the ILEC's stock of poles, in effect, would have lost 20 percent of its economic value. The depreciation rates used in HM 5.3 Revised completely disregard this fact.

Deleted: HM 5.3

1 A. The various releases of the HAI Model share a number of similarities with respect to
2 network design. Each of the releases presented in Washington UNE cost proceedings to
3 estimate Verizon NW's costs start with geographic areas (and associated information
4 such as the number of lines, households, businesses, and the like) that were intended --
5 though failed -- to represent the distribution areas that accepted telecommunications
6 engineering practices would produce. In all releases, these areas were developed *prior*
7 *to* their inclusion in the HAI Model.³¹ In Verizon NW's previous UNE proceeding before
8 this Commission, the census block groups ("CBGs") used by HM 3.1 were allegedly
9 representative of distribution areas (i.e., they were considered to be representative of
10 certain aspects of engineering practice, particularly the number of households served in
11 a single distribution area). In later releases, beginning with HM 5.0 and including HM 5.3
12 Revised, an outside firm (TNS Telecoms or "TNS") developed "clusters;" and again,
13 although certain engineering criteria apparently changed between the various releases of
14 the HAI Model, they were determined by the HAI Model sponsors to be consistent with
15 proper engineering practice. That is, the geographical areas (CBGs in earlier iterations
16 and clusters in the later releases) were intended to represent the areas to which a
17 telephone engineer would design and build outside plant.

Deleted: HM 5.3

18 These geographical areas are developed outside of the Model, and the
19 documentation purportedly describing their development fails to provide the information
20 necessary to verify whether the geographic areas in fact reasonably represent what
21 would result from sound engineering practice or, for that matter, whether they accurately

³¹ See Mercer Supplemental Direct at p. 9. As discussed in more detail below, some of the most fundamental network design assumptions are hard-wired into the database that represents distribution areas, and thus cannot be modified within HM 5.3 Revised.

Deleted: HM 5.3

Formatted: Right

1 represent the locations to which a carrier would build telecommunications facilities (e.g.,
2 whether the facilities' routes are the proper length). Subsequent to AT&T/MCI's January
3 2004 re-filing, Verizon NW gained access to certain aspects of the incredibly complex
4 and time-consuming data and processes used by TNS to transform the data provided by
5 Verizon NW (and other data maintained by TNS) into the geographic inputs used in HM
6 5.3 Revised. Mr. Dippon's Reply Declaration describes the evaluation of those data and
7 processes, and concludes that, because the clusters produced by HM 5.3 Revised are
8 so far removed from any reasonable depiction of Verizon NW's distribution areas, they
9 could not possibly produce accurate estimates of Verizon NW's forward-looking costs of
10 providing UNEs.³²

Deleted: HM 5.3

Deleted: HM 5.3

11 **Q. PLEASE DESCRIBE THE SIGNIFICANCE OF THESE CLUSTERS TO HM 5.3**
12 **REVISED'S OVERALL NETWORK DESIGN.**

Deleted: HM 5.3

13 **A.** These clusters form the basis upon which HM 5.3 Revised's UNE cost estimates are
14 calculated -- i.e., the lengths of facilities' routes (e.g., how much feeder plant is needed
15 between a wire center and the center of a distribution area) and the types and amounts
16 of plant (e.g., how much copper cable of particular size, and what type of associated
17 support structure are needed by a firm with the luxury of building facilities on a "blank
18 slate" to serve Verizon NW's current volumes of demand at their actual locations. Once
19 those quantities are determined, various inputs (e.g., the cost of an installed telephone
20 pole) are used to determine the total investment putatively required to efficiently provide
21 telephone service.

Deleted: HM 5.3

³² Dippon Reply Testimony at Section V.

Formatted: Right

Deleted: HM 5.3

1 HM 5.3 Revised then makes other calculations, including determining the annual

2 capital charges associated with the investment, annual maintenance expenses, and
3 various "overhead" expenses not directly tied to the network investment. Even if the
4 cluster input data were accurate, the validity of the investment and associated costs

5 produced by HM 5.3 Revised depends on whether the quantities produced by the Model,
6 and the price inputs used to produce the investments, comport with what Verizon NW (or

7 any other real-world carrier) could reasonably expect to achieve. To the extent the
8 "blank slate" (1) fails to represent proper engineering design and decisions, (2) ignores
9 real-world constraints that an actual carrier would face (e.g., routes cannot be direct
10 because rights-of-way are not ubiquitous, carriers need adequate capacity to avoid
11 service disruptions, etc.), (3) inaccurately represents the necessary facilities (e.g., cable

12 sizes and support structures), and/or (4) overlooks the fact that carriers cannot always
13 purchase and install equipment under the favorable terms that HM 5.3 Revised assumes

14 a fictitious "blank slate" carrier would enjoy, the UNE cost estimates produced by HM 5.3
15 Revised will not represent those that would prevail under competitive conditions. To the
16 contrary, the cost estimates produced will be, at best, imprecise and unrealistically low.

17 **Q. HOW IS THE REST OF YOUR TESTIMONY ORGANIZED?**

18 **A.** The rest of my Reply Testimony is organized as follows. In the next section, I discuss
19 how information about locations of facilities should be translated into a network design. I

20 then provide several tests, which demonstrate that HM 5.3 Revised produces

21 unreasonably low UNE cost estimates. Next, I identify a number of major changes in
22 outside plant inputs that produce unrealistically low costs and, as Mr. Murphy explains,
23 do not match the costs that a real-world carrier would incur. I then discuss specific

1 modeling issues, including certain features that appear to be inconsequential in
2 Washington, and particular aspects of the Model that produce inaccurate and/or
3 insufficient investment estimates. I then explain why the expense factors proposed by
4 AT&T/MCI produce levels of operating and related expenses that are implausibly low
5 relative to Verizon NW's current levels. Next, I discuss the results of the regulatory
6 scrutiny that AT&T/MCI offer in support of HM 5.3 Revised and demonstrate that they
7 have failed to address the specific concerns raised by this Commission, as well as other
8 state regulatory commissions, with respect to previous versions of the HAI Model. I then
9 identify and criticize a number of HM 5.3 Revised's critical inputs and their sources. The
10 final section summarizes my conclusions.

Deleted: HM 5.3

Deleted: HM 5.3

11 **IV. TRANSLATING CUSTOMER LOCATION INFORMATION INTO A VIABLE NETWORK**
12 **DESIGN**

13 **Q. IS HM 5.3 REVISED'S APPROACH TO LOCATING CUSTOMERS AND DESIGNING A**
14 **NETWORK REALISTIC?**

Deleted: HM 5.3

15 **A.** No. Implicit in Dr. Mercer's claim that HM 5.3 Revised is the best model for estimating
16 Verizon NW's forward-looking costs is the proposition that any model that *claims* to
17 construct routes between customers and end-offices (loop plant), and end-offices to
18 each other (interoffice facilities), is inherently superior to a model that starts by
19 measuring some features of the current network and makes appropriate forward-looking
20 adjustments. Such a claim does not withstand careful scrutiny, and has been rejected by
21 a number of state regulatory commissions.

Deleted: HM 5.3

22 Based on the alleged superiority of a completely hypothetical and highly abstract
23 network, AT&T/MCI embark on what has proven to be an almost impossible task:

1 designing the network of a hypothetically “efficient firm” and dictating what that firm
2 would pay for that network, telephone pole by telephone pole, wire by wire, switch by
3 switch, and so forth. This undertaking is tantamount to a competitive bid for a contract to
4 build Verizon NW’s entire Washington network overnight without any financial
5 commitment to do so, and without engaging in any type of sanity check (e.g., are the
6 routes long enough; are there sufficient amounts of network components; does the
7 network design account for *all* the costs a firm would incur in providing UNEs?).

8 AT&T/MCI merely assert that the “least cost” algorithms that draw loop routes (i.e.,
9 TNS’s development of clusters as a preprocessing step to HM 5.3 Revised, as well as
10 the development of interoffice rings by another computer program) are TELRIC-
11 compliant, and contend that the judgment of their engineering team is sufficient to
12 determine not only how a firm will build and operate its network on a going-forward basis,
13 but also what that firm can expect to pay for all of its network components.

Deleted: HM 5.3

14 **Q. HOW WOULD ONE GO ABOUT TESTING THE REASONABLENESS OF HM 5.3’S**
15 **NETWORK DESIGN?**

16 **A.** To assess the reasonableness of HM 5.3 Revised’s network design, it is useful to
17 consider what a “plan” for a new network would entail. It is necessary that: (1)
18 customers are connected to end-offices; and (2) the distribution terminal, which is the
19 end of the loop plant closest to the customers (e.g., on a telephone pole), is close to
20 where actual customers are located. These propositions are unaffected by whether the
21 routes of the current network are more or less efficient than a completely redesigned
22 network, as there is no reason to believe that distribution terminal locations could be
23 more efficiently placed.

Deleted: HM 5.3

Formatted: Right

1 Accordingly, a first step in evaluating the results of a cost model would be to
 2 assess how distribution terminals are located. HM 5.3 Revised does not explicitly locate
 3 these terminals. Instead, it employs the following process that can, at best, provide a
 4 rough approximation of where these terminals are located: (1) start with a rectangular
 5 representation of the distribution areas that TNS has provided,³³ (2) divide these
 6 rectangles into "lots;" and (3) place distribution terminals at lot boundaries, e.g., at the
 7 hypothetical locations of telephone poles.³⁴ In contrast, Verizon NW's cost model starts
 8 with the actual locations of most of the distribution terminals used to serve the customers
 9 both models are designed to include. The distribution terminals whose locations could
 10 not be identified are assigned a location that corresponds to an actual point in the
 11 network serving them. Thus, from the outset, Verizon NW's cost model starts with
 12 superior information concerning the portion of the network located nearest to the end-
 13 users to be served.³⁵

Deleted: HM 5.3

14 Once distribution terminals have been located, a cost model should group these
 15 terminals into distinct distribution areas, presumably based on current network design
 16 principles. Again, the contrast between HM 5.3 Revised and Verizon NW's cost model is
 17 striking -- the proponents of HM 5.3 Revised assert that the generalized engineering

Deleted: HM 5.3

Deleted: HM 5.3

³³ Mr. Dippon's Reply Testimony shows that, while HM 5.3 Revised treats distribution areas as rectangles, the customer locations in these areas can actually be contained in highly irregular shapes. Dippon Reply Testimony at Section V.

Deleted: HM 5.3

³⁴ In fact, HM 5.3 Revised only partially carries out this process. For example, the costs for distribution terminals are developed on a per-line basis for the entire cluster, with none of the customer location information (apart from lines) being used to estimate distribution terminal costs.

Deleted: HM 5.3

³⁵ The HM 5.3 Revised model developers claim that they have accurately identified actual customer locations. Whether or not this claim is justified is a moot point since, as is explained below, HM 5.3 Revised does not model a network that connects actual customer locations. Instead, the Model rearranges the locations into a rectangular grill.

Deleted: HM 5.3

Deleted: HM 5.3

Formatted: Right

1 rules supplied by Mr. Donovan,³⁶ and allegedly understood and correctly implemented by
 2 TNS, produce more efficient distribution areas than Verizon NW's current areas. The
 3 sponsors of HM 5.3 Revised in effect argue that: (1) Verizon NW, with the luxury of
 4 starting over today, would group distribution terminals into distribution areas that are
 5 different than those existing in the real network; (2) Mr. Donovan's unsubstantiated
 6 opinions completely and correctly represent the process by which terminal locations
 7 would be grouped; (3) TNS has correctly represented Mr. Donovan's assumptions; and
 8 (4) distribution facilities would consist of simple rectangular "grills" containing branch and
 9 backbone cables of generally uniform size throughout the cluster (e.g., all branch cables
 10 are 50-pair), without regard to the actual customer locations or the locations of existing
 11 rights-of-way. What the supporters of HM 5.3 Revised ignore, however, is that real-world
 12 network designers face constraints that are not represented in Mr. Donovan's
 13 assumptions or TNS's algorithms. These constraints include, but are not limited to, the
 14 locations of roads and rights-of-way, natural and man-made barriers, and unevenly
 15 distributed lots within distributions areas. In contrast to HM 5.3 Revised, Verizon NW's
 16 cost model starts with the distribution areas in its existing network, thereby recognizing
 17 the right-of-way constraints of the real world, as well as the uneven distribution of
 18 customer locations.

19 **Q. ARE THERE SIMILAR PROBLEMS ASSOCIATED WITH HM 5.3 REVISED'S**
 20 **MODELING OF FEEDER PLANT?**

³⁶ Messrs. Murphy and Richter describe how these abstract rules depart from standard network engineering practice and, as a result, produce distribution areas that bear little resemblance to those of an efficient real-world local exchange carrier.

Formatted: Right

Deleted: HM 5.3

Deleted: HM 5.3

Deleted: HM 5.3

Deleted: HM 5.3

Deleted: HM 5.3

1 **A.** Yes. A cost model should design feeder routes that run between the end-offices and the
 2 serving area interfaces (“SAIs” or cross boxes) located within each distribution area.
 3 Again, HM 5.3 Revised's claim to greater efficiency rests on the unsubstantiated
 4 assertion that: (1) TNS's and HM 5.3 Revised's algorithms for locating SAIs provide a
 5 more efficient design than Verizon NW's current network; and (2) HM 5.3 Revised's “right
 6 angle” feeder routing algorithms produce routes that are more efficient than what Verizon
 7 NW's engineers have designed. Neither assumption is correct. HM 5.3 Revised's
 8 unrealistic network design principles ignore real-world constraints and have never been
 9 validated against actual measurements based upon actual operating conditions. In
 10 particular, as Mr. Dippon explains in detail, not only does HM 5.3 Revised model
 11 significantly fewer distribution areas and place substantially fewer SAIs than Verizon NW
 12 has in its Washington network, but the hypothetical locations of the SAIs are often not
 13 closely aligned with the customer locations they purportedly serve.³⁷ Similarly, the “right
 14 angle” routing of feeder routes ignores any and all obstacles that may be present along
 15 the two, hypothetical, straight-line segments connecting the wire centers to SAIs.³⁸

16 **Q. IS A COMPARISON OF RELATIVE LOOP DISTANCES SUFFICIENT TO**
 17 **UNDERSTAND THE AMOUNT OF NETWORK EQUIPMENT REPRESENTED BY THE**
 18 **TWO COST MODELS?**

³⁷ Dippon Reply Testimony at Section V.

³⁸ HM 5.3 Revised assumes that feeder routes consist of a main feeder segment that may connect several clusters and subfeeder routes perpendicular to the main feeder routes. Direct routing (i.e., no accommodation for obstacles) is assumed for both main and subfeeder routes. And the feeder and subfeeder segments tend to be long -- averaging on the order of 1.7 miles of putatively unobstructed distance.

Deleted: HM 5.3

1 A. No. Dr. Mercer attempted such a comparison during a recent workshop in California.³⁹
2 However, while distances such as feeder route lengths are important in determining the
3 amounts of equipment to deploy (e.g., the number of telephone poles and the copper
4 cable lengths), the mix of these components is also important in determining total
5 investment and the resulting monthly costs. For example, the amounts of network
6 components for a one-mile stretch of a loop route can vary in their support structure
7 (e.g., poles versus buried), the size of the cables along the route, and so forth. These
8 differences, in turn, can produce important differences in costs. As I explain in detail
9 below, there are large variations in the cost per foot of cable and associated support
10 structure. Therefore, if HM 5.3 Revised selects an unrepresentative mix, the cost
11 estimates produced by the Model would be inaccurate. For example, if the Model placed
12 too much outside plant in low density clusters, but offset this error with too little outside
13 plant in high density areas, the average distances could be fairly close to realistic values,
14 but the distribution of costs among the density zones would be skewed.

Deleted: HM 5.3

15 Q. **HOW DOES HM 5.3 REVISED DETERMINE ROUTE LENGTHS AND THE NETWORK**
16 **COMPONENTS FOR THESE ROUTES?**

Deleted: HM 5.3

17 A. It is a two-step process. First, as Mr. Dippon describes in detail, the preprocessing
18 performed by TNS establishes the broad outlines of the HM 5.3 Revised network -- i.e.,
19 the number and sizes of distribution areas, their density classification (to establish the
20 costs of certain inputs), the total route distance (i.e., the strand distance) within each

Deleted: HM 5.3

1 distribution area, the number and types of lines, and so forth.⁴⁰ The equipment deployed
2 along these routes is then determined within HM 5.3 Revised itself.

3 **Q. DOES HM 5.3 REVISED “BUILD” TO THE ROUTES THAT TNS HAS DETERMINED?**

4 **A.** No. Although in determining the strand distances,⁴¹ TNS in principle has traced routes
5 from the putative SAI for a distribution area to the locations of every customer, HM 5.3
6 Revised does not use any of this information. Rather, the Model builds a rather simple
7 “grill” within a rectangular area. The grill contains a certain amount of “backbone” cable
8 of unknown sizes,⁴² and another amount of “branch” cables, all having the same number
9 of pairs. When the default strand distance constraint is employed, the Model then scales
10 the sum of the “backbone” and “branch” route distances (and, if applicable, connecting
11 routes) to equal the strand distance determined by TNS.

12 **Q. HAVE YOU EXAMINED SOME OF THE RESULTS OF THIS PROCESS?**

13 **A.** Yes. Perhaps the most significant feature of the clusters produced by TNS is their large
14 size, which as Mr. Dippon emphasizes cannot be changed in any fundamental way by
15 modifying HM 5.3 Revised.⁴³ Moreover, in building to such large areas, HM 5.3 Revised
16 tends to select equipment sizes that are also too large. For example, while HM 5.3
17 Revised produces about 1,100 SAIs⁴⁴ averaging 2,300 lines, VzLoop produces 3,300

⁴⁰ Dippon Reply Testimony Section IV.

⁴¹ The strand distance is generally the minimum length required to connect customer locations to the SAI location. According to HM 5.3 Revised's documentation, right-angle routing is used in determining these lengths.

⁴² The Model selects a particular back-bone cable size (e.g., 900-pair) at the SAI, which is assumed to taper in some unspecified manner so that the total cable investment is generally 65 percent of the amount without tapering.

⁴³ Dippon Reply Testimony at Section V. In particular, by allowing the clustering process to proceed to the point where the number of lines within, and the spatial dimensions of, clusters can be large, TNS's distribution areas differ from what engineers typically design in the real world, as Mr. Murphy explains in detail.

⁴⁴ This number is somewhat larger than the number of clusters produced by TNS because, in some cases, HM 5.3 Revised places multiple SAIs within a cluster.

Formatted: Right
Deleted: HM 5.3

1 SAls averaging 1,400 lines.⁴⁵ Similarly, while HM 5.3 Revised places about 1,100
2 remote terminals (“RTs”) averaging about 1,100 lines each, VzLoop places about 2,760
3 RTs averaging about 370 lines.

4 **Q. HAVE YOU EXAMINED CABLE SIZES?**

5 **A.** Yes. In general, HM 5.3 Revised's simplistic use of a “grill” to design distribution plant
6 results in relatively few cable sizes (e.g., 25-pair, 50-pair, etc.) being deployed within
7 distribution areas. And like SAls and RTs, these cables tend to be larger than those
8 represented by VzLoop. Figure 1 shows how the ratio of the average distribution cable
9 size produced by VzLoop and HM 5.3 Revised varies with the number of lines in a wire
10 center.

Deleted: HM 5.3

Deleted: HM 5.3

⁴⁵ In contrast to VzLoop, which produces a file with an inventory of the specific pieces of equipment placed within each wire center, HM 5.3 Revised does not report such components. I derived the quantities reported here by performing additional calculation on an intermediate file that can be produced by interrupting a HM 5.3 Revised run. To put the large SAl size into perspective, in the large Bothell wire center, 19 of the 38 SAls placed by HM 5.3 Revised are of the largest (7,200-line) size and account for 68 percent of the total SAl capacity. In contrast, only 22 of the 135 SAls placed by VzLoop are of the largest (5,400-line) size and account for only 35 percent of the total SAl capacity. Indeed, the *average* SAl capacity placed by HM 5.3 Revised for this wire center is 5,300, or almost the *maximum* capacity ever utilized in VzLoop.

10

The fact that the majority of these ratios are less than 1.0 demonstrates that **HM 5.3 Revised** produces larger cables,⁴⁶ which as I explain below, are less costly on a per loop basis. Smaller wire centers (which tend to be in lower density areas) are an exception to

⁴⁶ Indeed, **HM 5.3 Revised** produces larger cables, despite the fact that its default inputs provide less spare capacity (implying smaller cable sizes than if more spare capacity was specified).

1 the general pattern -- in such areas, HM 5.3 Revised's average distribution cable sizes
2 tend to be smaller, thereby producing relatively higher costs for smaller wire centers.⁴⁷

Deleted: HM 5.3

3 **Q. WHAT EFFECT DO HM 5.3 REVISED'S LARGE DISTRIBUTION AREAS HAVE ON**
4 **THE COST ESTIMATES PRODUCED BY THE MODEL ?**

5 **A.** From a costing standpoint,⁴⁸ Mr. Donovan has generally selected inputs that assume
6 economies of scale for larger items (e.g., the cost per pair tends to decrease as cable
7 sizes increases).⁴⁹ Consequently, the fact that HM 5.3 Revised tends to produce large
8 distribution areas results in unrealistic scale economies, and consequently low
9 investments and understated UNE cost estimates. That is, because the cost per unit of
10 larger equipment (e.g., the cost per pair foot for a large cable) is lower in many cases
11 than the costs for smaller equipment, the resulting costs (e.g., the costs for the number
12 of pair feet needed to serve an area) would be too low. For example, the larger copper
13 distribution cable sizes produced by HM 5.3 Revised result in an average investment per

Deleted: HM 5.3

Deleted: HM 5.3

⁴⁷ The average cable sizes of each of the respective models in each of the Commission's five current UNE rate zones also demonstrate that generally larger cables are deployed by HM 5.3 Revised. The following table shows these results:

Deleted: HM 5.3

UNE Zone	Lines	Average HM Distribution Cable (pairs)	Average VZ Distribution Cable (pairs)
1	286,386	456	292
2	268,451	364	279
3	102,441	264	195
4	197,450	215	157
5	209,488	103	94

Deleted: 453

Deleted: 338

Deleted: 255

Deleted: 213

Deleted: 100

Only in Zone 5, the highest cost/least dense zone, are the average cable sizes even remotely comparable.

⁴⁸ Messrs. Murphy and Richter discuss, from an engineering perspective, the problems associated with modeling large distribution areas.

⁴⁹ For example, the cost per pair for a 50-pair cable assumed by HM 5.3 Revised is about twice that of a 200-pair cable and about three times that of a 400-pair cable.

Deleted: HM 5.3

Formatted: Right

1 pair foot that is *twenty percent lower* than the corresponding average that VzLoop's
2 cable size mix would produce when Mr. Donovan's cable investment inputs are used.

Deleted: HM 5.3

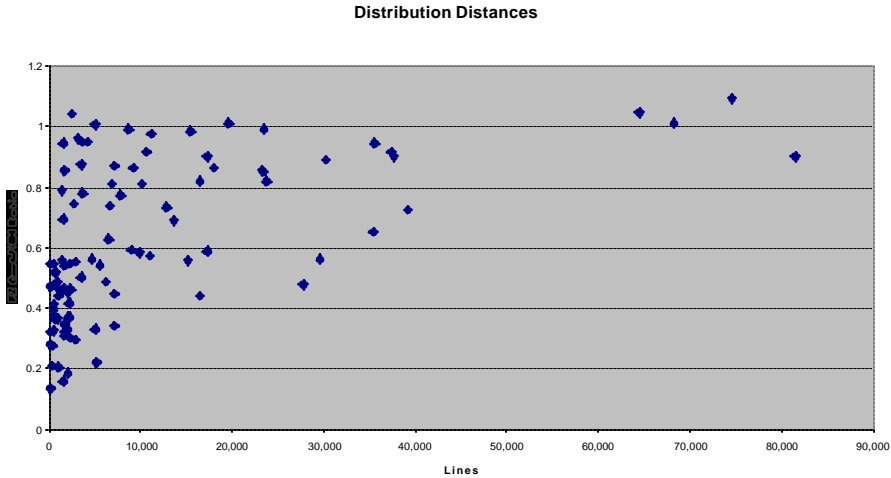

3 **Q. DO YOU HAVE OTHER OBSERVATIONS REGARDING HOW HM 5.3 REVISED AND**
4 **VzLOOP DEPLOY DISTRIBUTION CABLE?**

5 **A.** Yes. The total cable lengths produced by the two models can differ substantially from
6 wire center to wire center, as shown in Figure 2.

Formatted: Right

1

Figure 2

2
3

4

5 This figure displays the ratio of the total copper distribution sheath distance produced by
6 VzLoop to the corresponding HM 5.3 Revised distance. The general pattern is that,
7 while HM 5.3 Revised tends to produce greater distances for smaller wire centers (as
8 indicated by low ratios), the ratios tend to be larger as wire center size increases.

Deleted: HM 5.3

Deleted: HM 5.3

Deleted: (indicated by ratios of less than 1.0), the opposite tendency applies to larger wire centers

9 Similar to the pattern for cable sizes, the cost implication of this outcome is that, relative
10 to VzLoop, HM 5.3 Revised overstates costs in low-density areas, but understates costs
11 in higher-density areas. Not surprisingly, it is the high-density areas where AT&T/MCI
12 are likely to purchase the majority of their UNEs.⁵⁰

Deleted: HM 5.3

⁵⁰ The total distribution distances (sheath feet) of each of the respective models in the Commission's current five UNE rate zones also demonstrate HM 5.3 Revised's general tendency for placing relatively greater proportions of facilities in low-density areas. The following table shows these results.

1 Q. WHY ARE HM 5.3 REVISED'S DISTRIBUTION AREAS SO LARGE?

2 A. In response to criticisms levied during the interim phase of the SBC California UNE
3 proceeding regarding the underground placement of RTs, Mr. Donovan changed both
4 the design of HM 5.3 Revised's distribution areas, as well as the available sizes of RTs,
5 to allow for the underground installation of RTs, but only in distribution areas with a
6 sufficient number of lines. However, rather than base the decision to place RTs
7 underground on local conditions (e.g., city ordinances), the sole determinant of
8 underground placement is the size of the cluster -- an RT is only placed underground in
9 a controlled environmental vault ("CEV") when a cluster requires more than 2,100 lines
10 of capacity. The design of the clusters was also changed from earlier versions of the
11 HAI Model (e.g., HM 5.0a) to allow for larger clusters that are able to accommodate
12 larger RTs. Specifically, because HM 5.3 Revised places RTs in underground facilities
13 only when demand exceeds Mr. Donovan's 2,100-line threshold, the high costs of
14 acquiring and installing underground structures are spread over a large number of lines,
15 thereby artificially, and unrealistically, reducing the cost per line of the equipment. This
16 stands in sharp contrast to the real world, where the placement of such structures are
17 dictated by factors such as zoning regulations, which are unrelated to the number of
18 lines. Contrary to the assumption made in HM 5.3 Revised, in the real network there is

1 no guarantee that the high fixed costs of underground structures can be averaged over a
2 large number of lines.

3 The drastic impact of Mr. Donovan’s use of CEVs to justify such large distribution
4 areas can be seen in the wide differences in RT sizes used by HM 5.3 Revised (which
5 are based on Mr. Donovan’s novel design recommendation)⁵¹ and the RT sizes used by
6 VzLoop (which are consistent with Verizon NW’s well-established engineering practices),
7 as Table 1 demonstrates. VzLoop has over twice the number of RTs (which is
8 consistent with the design of a network with smaller distribution areas). As a result, the
9 average size of an RT in VzLoop is only about one-third of that produced by HM 5.3
10 Revised. Indeed, over 60 percent of the RT capacity in HM 5.3 Revised is accounted for
11 by CEVs – alternatives that were not even considered in earlier versions of the HAI
12 Model. These contrasts illustrate a critical issue in assessing the validity of HM 5.3
13 Revised versus VzLoop: HM 5.3 Revised relies upon a novel and untested “theory” that
14 “bigger is better,” whereas VzLoop utilizes a design that reflects proven practices
15 actually employed in designing a real-world network.

3 Q. PLEASE SUMMARIZE YOUR CONCLUSIONS WITH RESPECT TO HM 5.3

4 REVISED'S MODELING APPROACH.

5 A. In sum, HM 5.3 Revised's claims of greater efficiency rest on: (1) the untested and

6 debatable proposition that competition would produce more efficient network designs

7 than exist today; (2) an assumption that the unverified and highly suspect data HM 5.3

8 Revised employs is accurate enough to locate key facilities, such as distribution

9 terminals, in a network; and (3) a belief that the abstract rules and erroneous algorithms

10 that HM 5.3 Revised employs could produce a realistic representation of a functioning

1 network. With respect to each and every point, AT&T/MCI are mistaken. Ironically,
2 despite the fact that HM 5.3 Revised's proponents tout the Model as being more efficient
3 because it is intended to, though in reality does not, produce a more efficient network
4 design, they often defend the Model on the basis that it produces *more* facilities than
5 other models produce and/or are present in the real network (e.g., longer loop lengths).⁵²
6 That is, the existing network, which they routinely condemn as inefficient (and out of
7 compliance with TELRIC rules), is used to justify the alleged realism of HM 5.3 Revised's
8 hypothetical network. Having failed to establish that HM 5.3 Revised produces a more
9 efficient design, the choice among models would seem to shift to whether a completely
10 hypothetical approach can be more accurate and reliable than one which is grounded in
11 measurements of a functioning network. The answer to that question is plainly, no.

Deleted: HM 5.3

Deleted: HM 5.3

Deleted: HM 5.3

12 **Q. IS VERIZON NW'S APPROACH TO COST MODELING CONSISTENT WITH THE**
13 **MODELING APPROACHES APPROVED BY THE FCC AND/OR STATE**
14 **REGULATORY COMMISSIONS?**

15 **A.** Yes. The FCC has explicitly approved methodologies like Verizon NW's approach to
16 cost modeling, which is based on the existing network with appropriate forward-looking
17 adjustments, and looks to current costs that Verizon NW actually pays for network
18 components such as switches. The FCC made clear when accepting BellSouth's
19 approach to modeling loop costs:

20 While BellSouth's loop model was based on a sample of existing
21 loops, the record demonstrates that loops were redesigned to reflect
22 forward-looking criteria rather than reproducing the existing network.

⁵² See e.g., Before the California Public Utilities Commission, Application Nos. 01-02-024, et al., *Declaration of Brian F. Pitkin in support of Joint Applicants' Rebuttal Comments* (March 12, 2003) at p. 49.

1 Also, the sample assumed that cable routes would follow existing
2 rights-of-way and roads that BellSouth would use today if it were to
3 place that cable.⁵³

4 Recent decisions by state regulators have also approved forward-looking cost
5 studies that start with measurements of an ILEC's existing network and, in doing so,
6 have rejected previous versions of the HAI Model. Thus, as I describe later, not only has
7 the regulatory scrutiny Dr. Mercer mentioned⁵⁴ failed to produce widespread acceptance
8 of the HAI Model, regulators at the same time have rejected AT&T/MCI's inaccurate
9 interpretation of TELRIC as well. For example, in accepting Verizon's cost study and
10 rejecting HM 5.2a, the Massachusetts Department of Telecommunications and Energy
11 found:

12 Therefore, because Verizon's reliance on existing network
13 architecture as the starting point can lead to reasonable cost results
14 provided that appropriate modifications are made to render the
15 network "more forward-looking," we find that the LCAM is a
16 reasonable tool for modeling UNE loop costs....

17 We find that Verizon has provided sufficient validation of the data it
18 uses to construct its LCAM model and that, with the appropriate
19 modifications to the assumptions about inputs, the existing network
20 configuration can be used to compute reasonable estimates of
21 forward-looking costs.⁵⁵

⁵³ BellSouth Order at ¶ 36 (footnotes omitted). In this paragraph, the FCC approved the determination of the Georgia Commission stating: "The Georgia Commission was not hesitant to apply adjustments to BellSouth's cost model to ensure cost-based rates consistent with TELRIC and a forward-looking approach. The evidence shows that the Georgia Commission deliberated over the loop sample methodology and corrected the omission of shorter multi-line business loops. The state commission, however, did not accept AT&T's criticism that BellSouth's loop sample 'improperly adjusted the loop characteristics to be forward-looking.'" In a footnote, the FCC noted that the adjustments included the forward-looking placement of DLC and fiber facilities, and changes in cable gauges -- adjustments that parallel those used in Verizon NW's cost study. The FCC released the BellSouth Order just two days after the Supreme Court upheld the TELRIC rules. See BellSouth Order at p. ¶ 22. Thus, there can be no doubt that an approach that accounts for the fundamental characteristics of existing networks fully complies with TELRIC.

⁵⁴ Mercer Supplemental Direct Testimony at pp. 6-7.

⁵⁵ Before the Massachusetts Department of Telecommunications and Energy, Docket No. D.T.E. 01-20, *Order* (July 11, 2002) at pp. 50-51.

1 Similarly, the New Jersey Board of Public Utilities (“New Jersey Board”) concluded:

2 We find that the Verizon NJ models are based upon sound
3 engineering principles and sound modeling concepts. While AT&T
4 has demonstrated that similar results may be obtained by varying
5 the inputs and assumptions contained in its model, we find that it is
6 more appropriate to modify the Verizon NJ models to produce
7 forward-looking, TELRIC-compliant results because its basic
8 construction more accurately replicates [Verizon NJ’s] network,
9 whereas the HAI Model employs a methodology designed to create
10 a least-cost, most efficient network without regard to realistic design
11 considerations...

12 Although in order to determine loop length and structure mix,
13 Verizon NJ takes into consideration characteristics of its outside
14 plant in each UAA, it does not develop its cost estimates based
15 upon embedded costs. In connection with making a decision
16 regarding cost model assumptions for reconstructing the local
17 network, the consideration of the layout and characteristics of the
18 existing network is a reasonable starting point. This is particularly
19 true in light of the fact that customer locations, street locations,
20 central office locations, natural barriers and right-of-way locations
21 will not change significantly.⁵⁶

22 Likewise, regulators in states such as New York,⁵⁷ Pennsylvania,⁵⁸ and Maryland⁵⁹ have
23 accepted cost studies offered by Verizon, which are similar to the ones that were
24 approved in Massachusetts and New Jersey.

25 Therefore, the first fundamental issue in this case is which approach is more
26 reliable: the Verizon NW approach, which starts with information concerning Verizon
27 NW’s current network architecture and makes realistic and appropriate forward-looking
28 adjustments, or the HM 5.3 Revised approach, which attempts to design a brand-new

Deleted: HM 5.3

⁵⁶ Before the New Jersey Board of Public Utilities, Docket No. TO00060356, *Decision and Order* (Mar. 6, 2002) at pp. 27, 30 (“New Jersey Order”).

⁵⁷ Before the New York Public Service Commission, Case 98-C-1357, *Order on Unbundled Network Element Rates* (Jan. 28, 2002).

⁵⁸ Before the Pennsylvania Public Utility Commission, Docket No. R-00016683, *Tentative Order* (Oct. 24, 2002).

⁵⁹ Before the Maryland Public Service Commission, Case No. 8879, *Order No. 78552* (June 30, 2003) at p. 17.

1 network from the ground up without any regard to real-world operating constraints or
2 accepted engineering criteria. Without having verified that their cost study produces
3 accurate results, AT&T/MCI essentially ask the Commission to: (1) trust TNS'
4 inadequately documented and, in some cases, undisclosed algorithms and processes for
5 producing clusters; (2) endorse the inaccurate methods of drawing "least cost" routes;
6 (3) rely on untested formulas to determine the equipment that is needed to provide
7 service on these routes; and (4) believe that unverified judgments are appropriate
8 support for the price of that equipment and the labor to install it. In contrast, Verizon
9 NW's modeling approach starts with information about a network that is the result of
10 years of growing competition and incentive regulation of some services, and that has
11 provided telecommunications services to real customers at locations where they are in
12 fact found. Verizon NW's cost model measures the key characteristics of that real-world
13 network and captures all the costs necessary to build it and maintain it, many of which
14 are easy to overlook and/or very difficult (if not impossible) to measure accurately (e.g.,
15 complying with zoning regulations) in a study such as ~~HM 5.3 Revised~~. Unlike ~~HM 5.3~~
16 ~~Revised~~, Verizon NW's modeling approach is grounded not in the speculation inherent in
17 an "optimization" algorithm or unverified input recommendations, but in the reality of
18 experience tested and refined over the years to accommodate the dynamic nature of the
19 telecommunications industry.

⁶⁰ The documentation for HM 5.3 Revised states that the density-zone Expense Modules "include a USOA Detail worksheet that breaks out investment and expense results by Part 32 Account for comparison with embedded ARMIS data." Mercer Supplemental Direct Testimony at RAM -4 (Model Description), p. 64. However, this worksheet (which has appeared in the various versions of the HAI Model from 1998 (5.0a) through 2003 (HM 5.3 in the SBC California proceeding)) is not included in the Model's output file. Thus, the Model documentation itself offers a relevant "sanity check" comparison, despite the fact that AT&T/MCI and their witnesses have tried to distance themselves from this Model output in the past (by insisting that all comparisons to actual network costs are irrelevant), and evidently have done away with it altogether in this proceeding. I have included the "USOA Detail" worksheet here, which accompanied the SBC California version of HM 5.3, and have updated it to include the investments associated with DS-1 and DS-3 UNEs. I have also reduced the general support investments and expenses in the ARMIS and current investment columns to match the proportions assigned to the UNEs modeled by HM 5.3 Revised in this proceeding.

1 **Q. PLEASE DESCRIBE THE RATIONALE FOR YOUR VARIOUS VALIDATION**
2 **TESTS.**

3 **A.** A proper benchmark for any cost model that purports to measure a carrier's
4 forward-looking costs is whether the model depicts enough equipment and
5 includes accurate prices for that equipment. Similarly, there must be a
6 sufficient amount of ongoing expenses to pay for the labor force needed to run
7 a complex network and cover the ongoing charges for materials that a carrier
8 routinely incurs. Because a cost model should realistically depict existing (or
9 planned) locations of switches and outside plant facilities and, consistent with
10 the FCC's TELRIC principles, the prices ILECs actually pay for their inputs,
11 unusually large deviations between the cost model and reality almost certainly
12 imply inaccuracies in the former, not inefficiencies in the latter. At a minimum, it
13 would seem imperative that a cost model's sponsors justify with specificity why
14 substantially fewer resources are needed and/or why facilities can be acquired,
15 or services can be delivered, at prices far below what a real-world carrier
16 currently pays.⁶²

⁶² As discussed in greater detail below, the New Jersey Board rejected HM 5.2a. Its primary concern was the Model's large understatement of investment and expenses:

Chief among our concerns is a fact pointed out by Verizon NJ that revealed that the HAI model assumes that Verizon's entire network could be constructed for less than one-third of Verizon NJ's existing investment and that it could be operated for approximately one-fifth of Verizon NJ's current operating expenses. Although we recognize that forward-looking investment and operating costs are likely to be less than embedded or current costs, the substantial nature of the difference between the HAI cost estimates and Verizon NJ's actual experience is indeed dramatic and suggests to the Board that the HAI Model may potentially understate forward-looking costs.

New Jersey Order at pp. 25-26 (internal citations omitted).

1 A useful analogy is the following: suppose a customer came to Verizon
2 NW with a request for a 75 percent discount on a large number of loops.
3 Assume also that this customer knew of a firm that had claimed to have a
4 considerably more efficient way to design loops (as HM 5.3 Revised claims)
5 and could get the necessary materials very cheaply (e.g., at the unrealistically
6 low prices advocated by AT&T/MCI). A real-world carrier like Verizon NW
7 would only accept such a discount if the firm that advertised the more efficient
8 way to design loops agreed to pay any cost difference should the design
9 understate the amount of material required or otherwise be unable to offer the
10 favorable advertised prices.

Deleted: HM 5.3

11 HM 5.3 Revised would fail this simple sanity check. In general, the
12 Model produces investment levels that are less than 30 percent of Verizon
13 NW's total current investment (and about 38 percent of Verizon NW's ARMIS
14 investments), and expenses for operating the network that are less than 40
15 percent of Verizon NW's current levels. For example, despite the fact that HM
16 5.3 Revised assumes a relatively greater proportion of aerial cable investment
17 than appears in Verizon NW's network,⁶³ the Model provides only about 27
18 percent of the pole investment that it would take to replace Verizon NW's
19 current poles at current prices. This can only mean that HM 5.3 Revised
20 provides substantially fewer poles and/or it assumes a pole cost that is much
21 lower than what is attainable in the real world -- either way, the Model's results

Deleted: HM 5.3

Deleted: 5

Deleted: HM 5.3

Deleted: 5

1 are highly suspect.⁶⁴ It is inconceivable that Verizon NW's actual forward-
2 looking costs could be up to 70 percent lower than its current costs.

3 **Q. PLEASE DESCRIBE THE RESULTS ILLUSTRATED BY TABLES 2A AND**
4 **2B.**

5 **A.** Table 2A compares Verizon NW's actual capital investment to HM 5.3
6 Revised's estimated capital investment. Table 2A shows that HM 5.3 Revised
7 produces *less than 30 percent* of Verizon NW's current investment in network
8 components. In fact, after applying the current cost-to-book cost ratios to
9 estimate reproduction costs, HM 5.3 Revised produces relatively more
10 investment in electronic switching (26 percent) than cable and wire facilities (22
11 percent). Similarly, HM 5.3 Revised produces a mere 29 percent of Verizon
12 NW's current support investment (for vehicles, office equipment, and the like).⁶⁵

13 The investment comparison also shows a noticeable shift away from
14 underground cable, which is generally the most expensive type of cable to
15 place and support. Despite the fact that Mr. Donovan started with ARMIS data
16 on Verizon NW's actual deployment of the various types of cable,⁶⁶ HM 5.3
17 Revised's investment in underground cable accounts for only 16 percent of the

⁶⁴ For example, the Model assumes that Verizon NW pays only about one-third of the cost of a telephone pole, while electric utilities and other carriers paying for the rest. In fact, as Mr. Murphy describes, the Commission-mandated attachment fees are much lower than the level of cost sharing assumed by HM 5.3 Revised's sharing inputs. Murphy Reply Testimony at Section IV.

⁶⁵ As explained herein, total current support investments and expenses have been reduced by the same percentage that HM 5.3 Revised uses to assign such costs to UNEs (as opposed to retail operations).

⁶⁶ Before the Washington Utilities and Transportation Commission, Docket No. UT-023003, *Direct Testimony of John C. Donovan on behalf of AT&T Communications of the Pacific Northwest, Inc. and WorldCom, Inc. and XO Washington, Inc.* (June 26, 2003) at p.13 .

1 total cable investment, compared to about 33 percent of Verizon NW's current
2 investment in cable.⁶⁷

3 Turning to the comparison of Verizon NW's actual expenses to HM 5.3
4 Revised's estimated expenses in Table 2B,⁶⁸ the Model produces only about 54
5 percent of Verizon NW's current plant-specific expenses (i.e., the annual
6 outlays required to maintain and repair the network). The comparison is
7 particularly revealing for digital switching expenses, where the Model estimates
8 that Verizon NW can maintain its switches for only 56 percent of the cost it
9 currently incurs -- that is, AT&T/MCI assume that Verizon NW can maintain its
10 current digital switching technology serving the same number of lines with only
11 about three-fifths of the workforce it now employs. Such an assumption is
12 simply implausible.

Deleted: HM 5.3

Deleted: 50

13 The expenses associated with circuit equipment are also unrealistically
14 low. Despite an approximate doubling in the proportion of lines that are
15 assumed to be served by fiber feeder, the Model produces only about 79
16 percent of the expenses that Verizon NW currently incurs.⁶⁹

Deleted: 77

⁶⁷ Mr. Murphy identifies at least three major causes for this phenomenon: the misclassification of certain portions of the modeled feeder plant as though it were distribution plant, the failure of HM 5.3 Revised to meaningfully identify indoor SAs resulting from the "all feeder" design, and the oversized "clusters."

Deleted: HM 5.3

⁶⁸ Because Verizon NW has only minimal investments and expenses associated with operator services and public telephone, these categories are not included in Table 2B. In addition, including them results in extremely unrealistically expense estimates. For example, HM 5.3 Revised estimates that the expenses associated with operator and public telephone services are over 2.5 times as high as the expenses for cable and wire facilities; when in reality they constitute only three percent of Verizon NW's cable and wire expenses.

Deleted: HM 5.3

⁶⁹ ARMIS reports that about 33 percent of Verizon NW's working channels had a fiber digital loop carrier in 2002. ARMIS Report 43-07. In contrast, the proportion of fiberfed loops in HM 5.3 Revised is 75 percent.

Deleted: HM 5.3

Deleted: 74

1 Q. HOW DO **HM 5.3 REVISED'S** INVESTMENTS COMPARE TO VERIZON NW'S
2 RECENT EXPERIENCE?

3 A. A comparison of Verizon NW's investment from 1997 to 2003 -- the time that
4 has elapsed since AT&T/MCI sponsored HAI Model, Release 3.1 in the
5 previous UNE proceeding -- illustrates the unrealistic investment and expense
6 levels assumed by **HM 5.3 Revised**. Over those six years, Verizon NW spent
7 about \$976 million on *additions* to its total plant-in-service. **HM 5.3 Revised**, on
8 the other hand, calculates somewhat less than that amount of investment --
9 ~~\$896~~ million⁷⁰ -- to construct *from scratch* Verizon NW's entire Washington
10 network. Similarly, for digital switching, while ARMIS data suggest that
11 investment in additions to digital switches totaled about \$165 million between
12 1997 and 2003, **HM 5.3 Revised** produces only \$117 million to provide entirely
13 new digital switches for all of Verizon NW's lines.⁷¹

Deleted: HM 5.3

Deleted: 838

Deleted: HM 5.3

Deleted: HM 5.3

14 Q. WHY DOES **HM 5.3 REVISED** PRODUCE SUCH LOW INVESTMENT
15 LEVELS?

⁷⁰ See Table 2A.

⁷¹ ARMIS Report 43-02 shows a total investment of about \$280 million for Verizon NW, which is about 59 percent of its lines in Washington. It is highly unlikely that digital switch manufacturers could survive given these dismal investment expectations. And, as FCC Chairman Michael Powell has noted, the health of these vendors is crucial to the economic fortunes of the telecommunications industry:

Economic recovery in the telecommunications space, as it is for the economy as a whole, rests on spurring capital expenditures. We need service providers buying switches and other equipment from the Nortels, Lucent and Ciscos, who are ever more distressed than the service industry. Such companies are innovators, the R&D arms that have kept the network at the cutting edge of the world. They must survive for our future.

Remarks of Michael K. Powell, Chairman, Federal Communications Commission, Goldman Sachs Communicopia XI Conference (Oct. 2, 2002).

(continued...)

1 A. There are at least two explanations for the low investment levels produced by
2 HM 5.3 Revised (1) HM 5.3 Revised models insufficient quantities and/or the
3 wrong type of material (e.g., cable and telephone poles) to provide service; and
4 (2) HM 5.3 Revised's prices for materials are unrealistically low. For example,
5 suppose the cost of a telephone pole was actually \$600 and Verizon NW
6 needed 500,000 poles to serve its customers. The required investment would
7 be \$0.3 billion (\$600 x 500,000). In contrast, if the Model provided only 200,000
8 poles at a cost of \$400, the associated Model investment would be only \$0.08
9 billion -- about 25 percent of the required investment.

Deleted: HM 5.3

Deleted: HM 5.3

Deleted: HM 5.3

10 In fact, both effects are present, with the price effect being generally
11 larger: HM 5.3 Revised typically produces smaller quantities than what Verizon
12 NW's current investment levels imply, and the materials price inputs used in HM
13 5.3 Revised are considerably lower than what can be inferred from actual
14 investment levels and available ARMIS plant statistics. The following table
15 shows the investment necessary to replace Verizon NW's outside plant facilities
16 at current prices as a multiple of HM 5.3 Revised's investment levels, as well as
17 the corresponding price and quantity multipliers.⁷² In terms of the telephone
18 pole example in the previous paragraph, the investment multiplier would be

Deleted: HM 5.3

Deleted: HM 5.3

Deleted: HM 5.3

(...continued)

⁷² The estimation of pole prices is straightforward. ARMIS Report 43-08 identifies the equivalent number of poles. Therefore, the investment per pole implied by 2003 ARMIS investment and the current cost-to-book cost ratio is simply the pole investment in Table 2A divided by the number of poles – a figure that can be compared directly to HM 5.3 Revised's pole investment input. For cable, I divided investment by sheath distance, which is reported directly in ARMIS, but which has to be calculated by interrupting HM 5.3 Revised at an intermediate point.

Deleted: HM 5.3

Deleted: HM 5.3

1 3.75 (0.3/0.08), the price multiplier 1.5 (600/400), and the quantity multiplier 2.5
2 (500,000/200,000).⁷³

be connected to the same wire centers at a cost of only ~~22~~ percent (1/4.5) of what it would cost to replicate Verizon NW's existing plant. Table 3 shows that the estimated quantities in Verizon NW's actual network are about ~~10-20~~ percent larger than what HM 5.3 Revised produces, and the materials prices are 3 to 4 times higher than HM 5.3 Revised's inputs.

Q. BESIDES SERVING AS A BENCHMARK, WHAT ADDITIONAL LIGHT DO THE INVESTMENT COMPARISONS YOU HAVE JUST SHOWN SHED ON THE APPROPRIATENESS OF USING HM 5.3 REVISED TO ESTIMATE VERIZON NW'S FORWARD-LOOKING COSTS OF PROVIDING UNES?

A. As I explain in detail below, because HM 5.3 Revised provides, for example, ~~27~~ percent of Verizon NW's current pole investment, the Model automatically reduces the expenses allegedly necessary to maintain them by the corresponding percentage. Such an assumption is flawed. Just because AT&T/MCI believe (based on a flawed survey of vendors operating outside Washington) that poles may be cheaper does not mean that Verizon NW's expenses to maintain them will be similarly reduced. There is no plausible explanation for HM 5.3 Revised's implication that just because a carrier might get a good deal on poles, those poles would be cheaper to maintain than poles purchased at less favorable prices. Both the notion that fewer poles are required (despite the greater prominence of aerial cable in HM 5.3 Revised), and the assumption that maintenance expenses would be automatically reduced by corresponding amounts, have no merit.

1 Q. TABLE 3 INDICATES THAT THE TOTAL CABLE QUANTITIES PRODUCED
2 BY **HM 5.3 REVISED** ARE SOMEWHAT SMALLER THAN WHAT ARMIS
3 IMPLIES. IS THE SAME TRUE FOR THE DIFFERENT TYPES OF CABLE?

4 A. Yes, but the deviations from current prices differ considerably for the different
5 cable types, as shown in Table 4.

6 TABLE 4

11 Of particular note here is the fact that **HM 5.3 Revised** prices underground
12 cable considerably lower than what Verizon NW's current investments imply. A
13 likely explanation is that, in **HM 5.3 Revised**, almost 40 percent of the total
14 underground route distance is accounted for by the two lowest density zones
15 (i.e., areas with line densities less than 100 lines per square mile). In contrast,
16 real-world underground facilities tend to be concentrated in high-density areas.
17 Again, relative to both reality and VzLoop, **HM 5.3 Revised** appears to shift
18 costs away from large, high-density wire centers and towards smaller areas.

Deleted: HM 5.3

19 Q. HOW DO **HM 5.3 REVISED'S** COST ESTIMATES COMPARE TO THE
20 COSTS REPORTED BY VERIZON NW IN THE FCC'S ARMIS DATA, AND TO
21 THE COSTS ESTIMATES PRODUCED BY VzCOST?

Deleted: HM 5.3

1 A. A comparison of HM 5.3 Revised's monthly loop costs to Verizon NW's 2003
2 actual loop costs (as described in Mr. Dye's testimony),⁷⁵ and to VzCost's
3 monthly loop costs, as shown in Table 5 below.

4 **TABLE 5**

	Investment	Monthly Capital Costs	Monthly Network Expenses	Other Expenses	Network + Other Expenses	Total Monthly Cost
<u>HM 5.3 Revised</u>	\$447.84	\$4.89	\$1.14	\$2.47	\$3.61	\$8.50
VzCost	\$1,114.84	\$21.78	\$6.30	\$5.59	\$11.89	\$33.66

Deleted: 3.21

Deleted: 7.64

5
6 Table 5 reports total loop investments, and breaks down the respective monthly
7 costs into capital costs (i.e., depreciation, return, and taxes), network expenses
8 (i.e., plant-specific expenses other than general support), and all other expenses.⁷⁶

9 While HM 5.3 Revised produces investments and monthly costs that are less than
10 40 percent, of Verizon NW's actual experience, VzCost shows investments and
11 expenses that, while somewhat different than actual values, are much closer. That
12 is, VzCost results are clearly in line with the previously stated expectations of MCI's
13 counsel, the United States Supreme Court, and the CLECs themselves that loop
14 facilities do not exhibit the potential for rapid cost reduction like other network
15 components, such as switching, and, in fact, may actually increase on a going-
16 forward basis.

Deleted: expenses

⁷⁵ Before the Washington Utilities and Transportation Commission, Docket No. UT-023003, *Reply Testimony of Terry R. Dye on behalf of Verizon Northwest Inc.* (April 20, 2004).

⁷⁶ Because Mr. Dye's calculations (which are based on ARMIS data) do not conveniently identify network expenses, only the capital costs and total expenses are shown.

1 Q. PLEASE DESCRIBE SOME OF THE OTHER VALIDATION TESTS YOU
2 HAVE CONDUCTED.

3 A. Another benchmark is the employment implications of the expenses estimated
4 by HM 5.3 Revised. Table 2B shows that HM 5.3 Revised produces total
5 operating expenses, less depreciation, of about \$68 million (\$33 million for
6 plant-specific and \$35 million for network operations, customer services, and
7 corporate operations). These expenses would consist of compensation for the
8 employees operating the network modeled by HM 5.3 Revised and payments
9 for “out-of-pocket” materials. In HM 5.3 Revised, these expenses apply to
10 wholesale operations captured in recurring charges only (i.e., they must be
11 attributable to UNEs). In particular, HM 5.3 Revised’s assumptions imply that
12 48 percent of total expenses are considered wholesale.

Deleted: HM 5.3

Deleted: HM 5.3

Deleted: 64

Deleted: 30

Deleted: 33

Deleted: HM 5.3

Deleted: HM 5.3

Deleted: HM 5.3

Deleted: HM 5.3

13 To estimate the number of employees needed to operate HM 5.3
14 Revised’s network, 2003 ARMIS data for Verizon NW show that: (1)
15 compensation accounted for about 26 percent of operating expenses, less
16 depreciation; and (2) the average compensation per employee was about
17 \$71,000 per year. Therefore, the estimated cost of labor compensation implied
18 by HM 5.3 Revised is (\$68 million x 0.26 =) \$17.7 million, and the implied
19 number of employees would be (\$17.7 million labor compensation/\$71,000 per
20 employee =) 250 employees.

Deleted: HM 5.3

Deleted: 3

Deleted: 6.8

Deleted: 16.8

Deleted: 240

Deleted: almost three

21 In contrast, because Table 2B shows Verizon NW incurred 2.6 times the
22 out-of-pocket expenses as HM 5.3 Revised produces, Verizon NW had a labor
23 force providing wholesale functions that was about 2.6 times that implied by HM

Deleted: HM 5.3

Deleted: three

Deleted: HM 5.3

1 5.3 Revised, or about 650 employees in 2003 in Washington.⁷⁷ That is, HM 5.3

2 Revised's results are equivalent to a claim that an "efficient carrier" could run its
3 wholesale operations (i.e., produce the same volumes of network elements that
4 Verizon NW provides to itself and to CLECs today) with only about a little more
5 than one-third of Verizon NW's current labor force.

6 **Q. PLEASE SUMMARIZE YOUR CONCLUSIONS WITH RESPECT TO THE**
7 **AFOREMENTIONED VALIDATION TESTS.**

8 **A.** As shown in the summary table below, acceptance of the investment and
9 expense levels produced by HM 5.3 Revised requires a belief that Verizon NW:

10 (1) could produce the same volumes of UNEs (e.g., loops and switching) with
11 total network investment (\$896 million) that is less than the amount Verizon NW
12 spent in six years (from 1997 to 2003) just for capital *additions* to its current
13 network (\$976 million); and (2) would incur only about 37 percent of the total
14 wholesale operating expenses and employ only about 37 percent of the
15 employees that Verizon NW needed to operate its real-world network in 2002.

16 This stark difference between the hypothetical blank -slate theory of HM 5.3
17 Revised and the reality of Verizon NW's operations demonstrates that HM 5.3
18 Revised models an entirely unrealistic network and produces substantially
19 understated cost estimates; it in no way implies that the latter is an inefficient
20 carrier.

⁷⁷ ARMIS Report 43-02 stated that there were about 2,500 employees for Verizon NW in 2003 (including its operations outside of Washington). Some of the efforts of these employees are for non-regulated, retailing, and non-recurring activities, the associated expenses for which I have estimated and removed from Verizon NW's actual figures.

B. CONSISTENCY WITH EXPECTATIONS AND PRIOR HYPOTHESES

Q. HOW DO THE COST ESTIMATES PRODUCED BY HM 5.3 REVISED COMPARE TO THE RESULTS OF PREVIOUS RELEASES OF THE HAI MODEL?

A. Testing HM 5.3 Revised's results against general expectations and/or hypotheses implicit in previous releases of the HAI Model provides yet another validation test, which further demonstrates the absurdity of the cost estimates advocated by AT&T/MCI. As noted earlier, MCI previously noted before the United States Supreme Court that the costs of network elements not involving computer components, such as the loop, are not decreasing (and may even be increasing).⁷⁸ In direct contrast, the per-line loop costs advocated by AT&T/MCI in several Was hington UNE proceedings have dramatically dropped, as shown in the following table.

TABLE 7

	Investment	Monthly Capital	Network Expenses	Other Expenses	Total

⁷⁸ Supreme Court Argument at pp. 74-75.

HM 3.1	\$705.09	\$8.87	\$1.28	\$4.44	\$14.58
HM 5.0a	\$614.93	\$7.74	\$1.13	\$3.75	\$12.62
HM 5.3 Revised	\$447.84	\$4.89	\$1.14	\$2.47	\$8.50

Table 7 lists loop investment, annual capital costs, network expenses (plant-specific expenses other than general support), and other expenses (general support, network operations, and corporate overheads). The table shows a reduction of about 42 percent (over seven years) in the cost per loop relative to HM 3.1. AT&T/MCI's changing loop price recommendations translate into annual rates of decline of about 7.4 percent, which, as I described earlier and as MCI's counsel explained to the United States Supreme Court, simply cannot be explained by any technological developments in loop technology.

Q. WHY HAS THERE BEEN SUCH A DRASTIC REDUCTION IN LOOP COSTS BETWEEN HM 5.3 REVISED AND PREVIOUS VERSIONS OF THE HAI MODEL?

A. The overall reductions in loop costs (shown in Table 7) reflect changes to both the inputs and the Model itself. In fact, when I used inputs from the previous versions of the HAI Model in the SBC California version of HM 5.3 (a daunting task that was probably only an approximation because of the differences in the number, definitions, and formats of the inputs),⁷⁹ HM 5.3 produced somewhat higher investments than the earlier versions, suggesting that, while HM 5.3 Revised may produce more outside plant facilities, any cost increase

⁷⁹ Before the California Public Utilities Commission, Application Nos. 01-02-024 et al., *Reply Declaration of Timothy J. Tardiff filed on behalf of SBC California* (Feb. 7, 2003) at pp. 34-35.

1 associated therewith has been more than offset by equipment price reductions,
2 such as Mr. Donovan's very understated cable price recommendations.

3 Indeed, when HM 3.1's cable costs are used in HM 5.3 Revised, the investment
4 per line increases to \$734 (compared to the \$448 and \$705 for HM 5.3 Revised
5 and HM 3.1 shown above), and when HM 5.0a's cable costs are used with HM
6 5.3 Revised, the investment per line increases to \$653 (compared to the \$448
7 and \$615 for HM 5.3 Revised and HM 5.0a shown above). That is, Mr.

8 Donovan's changing engineering and installation labor estimates looms large in
9 explaining the changes in costs between successive versions of the HAI Model.

10 **Q. IN PARTICULAR, WHY DO HM 5.3 REVISED'S REDUCTIONS IN LOOP
11 COSTS DEFY COMMON SENSE?**

12 **A.** As AT&T/MCI have recognized in other contexts, labor accounts for substantial
13 amounts of the investment in loop facilities; and labor costs are not
14 decreasing.⁸⁰ Another major component of loop plant -- copper cable -- has
15 experienced recent price increases as well. The average monthly price of
16 copper increased from \$0.76 to \$1.34 between March 2003 and March 2004.⁸¹

17 Indeed, when the FCC developed the expense factors used by HM 5.3 Revised,
18 it *increased* book investments for loop investment categories when it estimated

Deleted: HM 5.3

⁸⁰ . . . [t]here is no reason why economic depreciation need conform to a pattern by which loss in plant value is most severe early and trails off late. While certain pieces of electronic telecommunications equipment (e.g., digital circuit equipment) may display such a characteristic, other pieces (e.g., copper or fiber cable, conduit systems) may not. Because of increases in engineering costs over time, such equipment may enjoy economic appreciation effects that attenuate any loss in value due to physical wear and tear.

Before the Federal Communications Commission, WC Docket No. 03-173, *Declaration of John C. Klick* (Dec. 16, 2003) at ¶ 107 ("FCC Klick Decl.").

1 the cost of current loop plant, as my results in Table 2A illustrate. If loops cost
2 were decreasing, one would expect to see the current cost lower than the book
3 cost, as illustrated by digital switching.

4 **Q. IS THERE ANY HISTORICAL PRECEDENT FOR THE HUGE COST**
5 **REDUCTIONS HM 5.3 REVISED IMPLIES?**

Deleted: HM 5.3

6 **A.** No. In an attempt to demonstrate that such huge differences between the cost
7 estimates produced by HM 5.3 Revised and Verizon's actual costs are
8 reasonable, AT&T/MCI have cited to the railroad industry and interstate long-
9 distances prices to support their contention that HM 5.3 Revised's implied
10 reductions to ILEC costs are not unreasonable.⁸² However, rather than support
11 the putative cost reductions that HM 5.3 Revised claims are feasible, the
12 railroad experience undermines such a claim. Indeed, those statistics show
13 that railroads reduced their *real* (inflation adjusted) costs (as measured by total
14 expenses per output) over a *twenty-year period* by less than what AT&T/MCI
15 claim could happen *overnight* for Verizon NW. In addition, Mr. Klick's
16 comparison with the railroad industry is not germane for two additional reasons.
17 First, it is likely that much of the improved performance for railroads was the
18 result of their shedding much of their (presumably unprofitable) network, a
19 luxury not available to ILECs such as Verizon NW. Second, while the railroad
20 gains reflect the full effect of deregulation, the potential for comparable gains in

Deleted: HM 5.3

Deleted: HM 5.3

Deleted: HM 5.3

(...continued)

⁸¹ In 1997 (when AT&T/MCI offered HM 3.1 to this Commission), the copper price was about \$1.07. The ups and downs in copper prices since then indicate that there is no reason to expect this component of loop costs will decline..

1 telecommunications is much less because of the long history of price cap
2 regulation, and the fact that ILECs have been subject to increasing amounts of
3 competition over the years. Both effects indicate that Verizon NW is already
4 operating at reasonably efficient levels; and thus, immediate 70-percent cost
5 reductions are totally unrealistic. Similarly, Mr. Klick reports that real long-
6 distance prices decreased by 23 to 41 percent after deregulation. However, a
7 substantial proportion of this reduction is attributable to the FCC's
8 contemporaneous reduction in access charges. When this effect is removed,
9 the resulting reduction in real long-distance prices (net of access changes) was
10 actually smaller than the real reduction in local telephone prices (net of
11 subscriber line charges).⁸³

12 **C. THE FCC'S SYNTHESIS MODEL DOES NOT VALIDATE HM 5.3**

Deleted: HM 5.3

13 **REVISED**

14 **Q. HOW DO THE RESULTS OF THE FCC'S SYNTHESIS MODEL COMPARE**
15 **TO THOSE OF HM 5.3 REVISED?**

Deleted: HM 5.3

16 **A.** Dr. Bryant describes some purported similarities between the FCC's Synthesis
17 Model and HM 5.3 Revised in an apparent attempt to lend credibility to the
18 latter.⁸⁴ In actuality, however, the Synthesis Model produces substantially

Deleted: HM 5.3

(...continued)

⁸² See, e.g., FCC Klick Decl. at ¶¶ 111-15.

⁸³ Before the Federal Communications Commission, WC Docket 03-137, *Declaration of Howard Shelanski and Timothy Tardiff on the review of rules for pricing unbundled network elements, prepared for filing with the Federal Communications Commission on behalf of Verizon*, (Jan. 30, 2004) at ¶ 14.

⁸⁴ Bryant Direct Testimony at pp. 16-17.

1 higher loop costs (close to \$19 per month and \$876 investment per loop) when
2 it is applied in a manner similar to that developed by the FCC for use in Section
3 271 proceedings.⁸⁵

4 Equally important, as MCI's counsel explained to the United States
5 Supreme Court:

6 The investment [from the Synthesis Model] is too low. And
7 the FCC specifically said it was too low...because it's
8 designed to calculate universal service subsidies at the
9 very most basic low level.⁸⁶

10 Consequently, any "fixes" developed for the FCC Synthesis Model's low
11 investment problem would only widen the gap between the UNE cost estimates
12 produced thereby and those calculated by HM 5.3 Revised. Contrary to Dr.
13 Bryant's assertions, rather than validate HM 5.3 Revised, the FCC Synthesis
14 Model confirms how incredibly understated the former's cost estimates truly are.

Deleted: HM 5.3

Deleted: HM 5.3

15 **VI. MAJOR CHANGES IN OUTSIDE PLANT LABOR REQUIREMENTS**

16 **Q. WHAT CHANGES, IF ANY, HAVE BEEN MADE TO HM 5.3 REVISED'S**
17 **MATERIAL PRICE INPUTS?**

Deleted: HM 5.3

18 **A.** The bulk of the material price inputs are presented in Mr. Donovan's testimony.
19 While Mr. Murphy evaluates them from an engineering perspective, I focus on
20 the labor requirement implications of the changes to these inputs. Apart from
21 the inputs for cable investment, digital loop carrier ("DLC") line cards, and
22 CEVs, Mr. Donovan presents the many materials prices that have not changed

⁸⁵ In particular, I used the FCC's default inputs for pct_1 sa and pct_DS -1 that assume two copper pairs per DS -1 service to make a comparable adjustment to the number of business and special access lines.

⁸⁶ Supreme Court Argument at p. 74.

1 among the various releases of the HAI Model. Since one would expect that
2 general inflation in labor and materials would increase outside plant materials
3 prices, by maintaining the same prices AT&T/MCI are able to produce
4 significantly understated cost estimates. Indeed, for the investments in loop
5 plant produced by HM 5.3 Revised, cable accounts for about 30 percent, DLC
6 equipment for about 27 percent, and the materials for which Mr. Donovan
7 maintained previous inputs (support structures, terminals, drops, NIDs, and
8 SAs) for 43 percent of the total loop investment.

Deleted: 9

Deleted: 4

Deleted: HM 5.3

9 **Q. PLEASE DESCRIBE THE CHANGES MADE BY MR. DONOVAN TO HM 5.3**
10 **REVISED'S CABLE INVESTMENT INPUTS.**

11 **A.** With regard to Mr. Donovan's new inputs for cable, he has replaced input prices
12 that combined materials, engineering, and labor with separate materials prices
13 (which he describes as coming from a Florida decision) and separate estimates
14 of the labor necessary to engineer and install cable. As shown in Table 8
15 below, Mr. Donovan has assigned substantially less cost to labor in HM 5.3
16 Revised than he recommended in previous versions of the HAI Model. For
17 cable sizes larger than 200 pairs, there is an even larger reduction relative to
18 the cable labor assumed in HM 3.1. The following table presents the
19 comparison for copper cable.⁸⁷

Deleted: HM 5.3

⁸⁷ The HM 5.3 Revised installed cable prices can be produced by interrupting an HM 5.3 Revised run at the point the distribution module is fully populated. The labor component is the difference between these total prices and the materials prices presented in Mr. Donovan's testimony. The labor components differ by type of placement. In order to facilitate a comparison with the HM 5.0a and HM 3.1 inputs (which do not differ by type of placement), I weighted them by the proportion of cable investment produced by HM 5.3 Revised for each type: 41.9 percent aerial, 51.5 percent buried, and

3 Such large decreases in labor costs are simply implausible.

4 **Q. HAVE YOU ATTEMPTED TO VALIDATE MR. DONOVAN'S PROPOSED**
5 **CABLE LABOR INPUTS IN ANY OTHER WAY?**

6 **A.** Yes. Another benchmark for Mr. Donovan's proposed cable labor inputs is to
7 determine their labor force implications. To do this, I compared the cable
8 investment produced by HM 5.3 Revised to an alternate run in which the cable
9 labor rates were changed from the default rate of \$60 to zero. The \$37 million

Deleted: HM 5.3...1 [34]

(...continued)

6.6 percent underground. For HM 5.0a's inputs (which are the same as cable costs in the later HM 5.2a), AT&T/MCI provided materials prices in response to Data Request 13-25 in the recent California UNE proceeding. Before the California Public Utilities Commission, Docket R. 93-004-03/I. 93-004-02, *Joint Commentors' Responses to Verizon's Thirteenth Set of Data Requests* (Nov. 7, 2002) at Response No. 13-25. These were subtracted from the HM 5.0a default cable prices. For the HM 3.1 cable inputs, labor costs were assumed to be 60 percent of the total installed cost.

Deleted: 8

1 difference in cable investment between the runs is the total labor payments for
2 engineering and installing all distribution and feeder cables (including DS-1 and
3 DS-3). At a rate of \$60, this means about 300 employees would be able to
4 engineer, splice and place on poles and in buried or underground facilities all
5 the cable necessary to serve Verizon NW's customers throughout the state of
6 Washington in one year -- a plainly unrealistic proposition. In other words,
7 within one year, these hypothetical employees could purportedly design and
8 place every piece of cable in every neighborhood in every city where Verizon
9 NW's 1.1 million loops are located.

Deleted: 260

10 Although not as convenient, it is also possible to estimate the labor
11 expenditures for installing other outside plant facilities (e.g., NIDs, drop wire and
12 terminals, support structures, and DLC equipment).⁸⁸ The result was a total of
13 about \$71 million, which is equivalent to less than 590 person years. That is,
14 within one year, fewer than 600 employees supposedly would be able to place
15 every NID, drop wire and terminal, erect all poles, dig every trench, and place
16 all DLC equipment in every neighborhood in every city where Verizon NW's 1.1
17 million loops are located. Again, such assumptions are simply implausible.

Deleted: 68

Deleted: 7

18 **Q. HOW DO THE FCC'S SYNTHESIS MODEL'S CABLE PRICES COMPARE TO**
19 **THE CABLE PRICES MODELED BY HM 5.3 REVISED?**

Deleted: HM 5.3

⁸⁸ For underground and buried trenching, and SAs, I used the labor content percentages provided in the HAI Inputs Portfolio ("HIP") (see Mercer Supplemental Direct Testimony at Attachment RAM-5, p. 162) to separate labor costs from materials. The manhole labor content was based on the HIP at pages 90 and 93. The labor content for DLC common equipment was based on Mr. Donovan's estimates in the SBC California proceeding. Before the California Public Utilities Commission, Application Nos. 01-02-024 et al., *Declaration of John C. Donovan in support of Joint Applicants' Rebuttal Comments* (Mar. 12, 2003) at p. 20.

Deleted: HM 5.3

1 A. The cable prices estimated by the FCC's Synthesis Model are 70 percent
 2 higher than the cable prices modeled by HM 5.3 Revised. In fact, since cable
 3 investment accounts for a substantial proportion of total loop investment, the
 4 FCC's inputs would obviously produce much higher loop costs regardless of the
 5 model in which they are used. Indeed, using the FCC's copper and fiber cable
 6 investment inputs (with no other input changes) in place of HM 5.3 Revised's
 7 inputs increases the investment per loop from \$448 to \$549 -- a result that
 8 increases the monthly cost by 24 percent from \$8.50 to \$10.55. In a recent
 9 UNE proceeding in Pennsylvania, the prices used in the Synthesis Model were
 10 endorsed by Mr. Riolo,⁸⁹ one of the original (and current) members of the HAI
 11 Model's engineering team.⁹⁰ It is inconceivable that any recent real-world
 12 changes can explain the large reduction in cable prices that AT&T/MCI assert
 13 are TELRIC-compliant in the instant proceeding.⁹¹

14 VII. SPECIFIC MODELING ISSUES

15 A. HM 5.3 REVISED IS NOT "INTEGRATED" AS AT&T/MCI ALLEGE

16 Q. DO YOU AGREE WITH DR. MERCER'S ASSERTION THAT HM 5.3 REVISED
 17 BENEFITS FROM THE INTEGRATION OF ITS VARIOUS COMPONENTS?

⁸⁹ Before the Pennsylvania Public Utility Commission, *Direct Testimony of Joseph P. Riolo On Behalf of AT&T Communications of Pennsylvania, Inc. and MCI WorldCom Network Services, Inc.* (Dec. 7, 2001) at p.13. Mr. Riolo lowered the fiber cable investment inputs, but only for interoffice facilities.

⁹⁰ Mr. Donovan reported that he had consulted with Mr. Riolo in preparation for the filing of HM 5.3 Revised in this proceeding. Before the Washington Utilities and Transportation Commission, Docket No. UT-023003, *Joint Responses of AT&T and MCI to Verizon's Second Set of Data Requests* (Aug. 4, 2003).

⁹¹ In fact Mr. Murphy reports that no "...significant changes in methods, procedures or technologies..." related to cable placement have occurred in about 25 years. Murphy Reply at p. 112.

1 A. No. In listing the purported advantages of HM 5.3 Revised, Dr. Mercer claims
2 that the various components of the Model -- i.e., ordinary POTS loops, high-
3 capacity loops, feeder facilities, end-office switches and interoffice facilities --
4 are integrated within HM 5.3 Revised.⁹² As a threshold matter, any benefits
5 from allegedly integrating various components are far outweighed by the highly
6 abstract and inaccurate nature of the Model. The mere existence of “bells and
7 whistles” that ostensibly make the Model more sophisticated are of minimal
8 value when the overall Model is unreliable.

9 In fact, Dr. Mercer’s assertion is overstated and the supposed benefits of
10 integrating components such as loop facilities, end-office switches, and
11 interoffice facilities are illusory. HM 5.3 Revised’s lack of integration is
12 demonstrated most notably by: (1) TNS’s creation of clusters completely
13 separate from, and entirely outside of, HM 5.3 Revised, and (2) the lack of
14 integration between feeder, distribution, and interoffice support structure, as
15 discussed below. Indeed, it seems impossible to “optimize” feeder plant and
16 interoffice facilities -- both of which are assumed to share 75 percent of their
17 common support structure -- when the former is determined by the TNS
18 preprocessing, and the latter are subsequently produced by an undocumented
19 Visual Basic program.

20 Yet another example of the un-integrated nature of the Model is provided
21 by HM 5.3 Revised’s modeling of interoffice transmission facilities. HM 5.3
22 Revised assumes that such facilities are 29 percent aerial, 27 percent buried,

⁹² Mercer Supplemental Direct Testimony at p. 12.

1 and 44 percent underground *in every zone*-- there is absolutely no variation
2 between zones. Accordingly, even in the two highest density zones where
3 facilities would normally be in underground conduit, HM 5.3 Revised assumes
4 that 56 percent of interoffice facility structure is on poles or simply buried in
5 trenches (and the price per foot is the same as what the Model assumes for the
6 lowest density for distribution and feeder structure).

Deleted: HM 5.3

7 In addition, like the overall Model itself, Dr. Mercer's alleged "integration"
8 is represented in a highly abstract manner -- e.g., by simply assuming certain
9 percentages of feeder structure can be shared with distribution. The Model
10 does not attempt to identify common routes where structure might be shared.⁹³

11 For example, in larger distribution areas, there would likely be many streets with
12 distribution cables that do not overlap with the single sub-feeder route depicted
13 by HM 5.3 Revised; therefore, the route sharing opportunities are
14 proportionately smaller than for areas with fewer distribution routes.

Deleted: HM 5.3

15 **Q. HOW MUCH IMPACT DOES HM 5.3 REVISED'S ATTEMPT AT**
16 **INTEGRATION HAVE ON THE COSTS AT&T/MCI HAVE PROPOSED IN**
17 **THIS PROCEEDING?**

Deleted: HM 5.3

18 **A.** Very little. Dr. Mercer's emphasis on integration stems from his apparent belief
19 that there are large savings to be had when different components of the
20 network (e.g., feeder and distribution) share structure (e.g., telephone poles and
21 buried trenches). To test whether this was the case in HM 5.3 Revised, I ran

Deleted: HM 5.3

⁹³ Before the California Public Service Commission, Docket R. 93-004-03/1. 93-004-02, *Workshop Transcript* (Jan. 15, 2004) at p. 3563.

1 two scenarios that removed all of the sharing assumptions from HM 5.3
2 Revised. Specifically, I changed the inputs that assume sharing between
3 distribution and feeder, and between feeder and interoffice routes, from their
4 defaults of 55 percent and 75 percent sharing, respectively, to zero. As a
5 result, the loop cost increased only slightly from \$8.50 to \$8.64, and the total
6 cost of network elements (which would reflect the cost of both input changes)
7 increased a comparably minimal amount, from \$15.44 to \$15.71.⁹⁴ To test the
8 impact of structure sharing between POTS and high -capacity facilities, I
9 changed the HM 5.3 Revised database so that all high-capacity lines had zero
10 demand. Removing this facilities' sharing -- in other words, effectively
11 assigning all structure costs to ordinary loops -- again increased the loop cost a
12 minimal amount (from \$8.50 to \$8.59).⁹⁵ The practical consequence of the
13 minimal impact of these highly-touted features is that their presence plainly
14 demonstrates the unreliable, and fundamentally flawed, nature of HM 5.3
15 Revised.⁹⁶

Deleted: 7.64

Deleted: 7.77

Deleted: 14.58

Deleted: 14.84

Deleted: HM 5.3

Deleted: 7.64

Deleted: 7.69

Deleted: HM 5.3

⁹⁴ The minimal impact could be due, in part, to the fact that the Model produces the illogical result that when the amount of sharing of interoffice structure with other utilities is reduced (i.e., Verizon NW purportedly incurs more of these costs), both the investment and monthly cost of an ordinary loop *decrease*. For example, when the proportion of sharing with other utilities decreases from the default assumption of 67 percent to no sharing, loop investment per line decreases from \$448 to \$441; and the corresponding monthly cost is reduced from \$8.50 to \$8.40.

Deleted: 404

Deleted: 398

⁹⁵ As Staff witness Spinks observes, the explicit treatment of high-capacity loops in HM 5.3 Revised distinguishes the Model from previous versions, e.g., such as HM 5.2a. The representation of high-capacity loops as multiple ordinary loops in the earlier versions of the substantially reduced ordinary loops costs, perhaps leading its proponents to the conclusion that HAI Model there should be large savings from sharing structures.

Deleted: 7.64

Deleted: 7.54

Deleted: HM 5.3

⁹⁶ An exhaustive explanation of why the inclusion of high-capacity loops has such a modest impact on ordinary loop costs would have to consider, among other things, the interactions among: (1) the impact of the flawed representation of how high-capacity loops are assumed to share outside plant and DLC facilities with ordinary loops (as described by Mr. Murphy), (2) the assumed levels of
(continued...)

1 Q. ARE THERE OTHER FEATURES THAT DR. MERCER DEEMED “HIGHLY
2 SOPHISTICATED” THAT HAVE A EQUALLY MINIMAL IMPACT ON
3 COSTS?

4 A. Yes. Part of the basis for Dr. Mercer’s assertion that HM 5.3 Revised is “highly
5 sophisticated”⁹⁷ appears to be the Model’s dubious “optimization” feature, as
6 well as other, similarly flawed, modeling techniques. However, as with the
7 sharing assumptions discussed above, these features have minimal to no effect
8 on cost. For example:

Deleted: HM 5.3

- 9 • The feature that is designed to optimize between aerial
10 and buried placement⁹⁸ only reduces loop costs by a
11 miniscule amount (0.07 percent).
- 12 • Ignoring terrain effects,⁹⁹ by setting them to the most
13 favorable conditions everywhere, causes only a 0.49
14 percent decline in loop costs, resulting in little more than
15 a four-cent change in unit costs.

Deleted: 8

Deleted: 52

16 In summary, some of the specific features that HM 5.3 Revised’s sponsors have
17 touted as extremely beneficial appear to be of minimal importance. In
18 particular, HM 5.3 Revised’s lack of sensitivity to how much sharing might take
19 place between various parts of the network clearly implies that AT&T/MCI’s
20 attempts to use such features to demonstrate the superiority of HM 5.3 Revised
21 over VzCost are essentially meaningless.

structure sharing with other utilities, and (3) the inputs used for structure and cable, particularly Mr. Donovan’s estimates of engineering and installation labor.

⁹⁷ Mercer Supplemental Direct Testimony at pp. 5, 30-31.

⁹⁸ Mercer Supplemental Direct Testimony at RAM-4 (HIP) at pp. 34-36.

⁹⁹ Mercer Supplemental Direct Testimony at RAM-4 (HIP) at pp. 40-42.

1 **B. SPECIFIC EXAMPLES WHERE THE HM 5.3 REVISED**
2 **CALCULATIONS PRODUCE INSUFFICIENT AND/OR**
3 **INACCURATE INVESTMENT**

4 **1. SAI SIZE LIMIT OPTION**

5 **Q. PLEASE DESCRIBE HM 5.3 REVISED'S NEW OPTION TO LIMIT THE**
6 **MAXIMUM SIZE OF AN SAI.**

Deleted: HM 5.3

7 **A.** Although AT&T/MCI recommend the use of large SAIs and large RTs or CEVs,
8 HM 5.3 Revised provides an option to limit the size of SAIs.¹⁰⁰ In contrast to the
9 typical placement of the SAI at the center of a distribution area, HM 5.3 Revised
10 purportedly can now place multiple, smaller SAIs within a given cluster.¹⁰¹
11 Curiously, Mr. Donovan has reported that this option would either modestly
12 increase cost,¹⁰² or have a slight impact in either direction.¹⁰³

Deleted: HM 5.3

Deleted: HM 5.3

13 **Q. DOES LIMITING THE MAXIMUM SIZE OF THE SAI HAVE THE EFFECT MR.**
14 **DONOVAN EXPECTED?**

15 **A.** No. Invoking the SAI size limit option produces a loop cost of \$7,88, noticeably
16 lower than HM 5.3 Revised's default result of \$8.50. Similarly, the average

Deleted: 26

Deleted: HM 5.3

Deleted: 7.64

¹⁰⁰ Model Description at p. 40. It should be noted, however, that a meaningful limit on RT capacity within distribution areas cannot be implemented within HM 5.3 Revised, but can only be imposed by re-running the TNS clustering process.

Deleted: HM 5.3

¹⁰¹ Mr. Murphy explains in detail why this option does not work and the counterintuitive results produced when the option is invoked. See also Murphy Reply Testimony for an explanation of why smaller clusters should produce increased feeder lengths but no change in distribution length.

¹⁰² Before the California Public Utilities Commission, Application Nos. 01-02-024 et al., *Workshop Transcripts* (June 25, 2003) at p. 655.

1 investment per loop decreases from \$448 to \$417, with the change due to
2 puzzling reductions in distribution cable and RT investments. This outcome
3 strongly suggests that the option has not been properly implemented, and may
4 be the product of input and/or algorithm errors.

5 2. SAI CAPACITY

6 **Q. DOES HM 5.3 REVISED MODEL SUFFICIENT SAI CAPACITY?**

Deleted: HM 5.3

7 **A.** No. Mr. Donovan's definition of distribution fill is the ratio of customer lines in a
8 cluster to the number of pairs in the backbone cables that terminate at the SAI.
9 Presumably, in order for those pairs to be available as spare capacity, there
10 needs to be room at the SAI to connect them. For example, if a distribution
11 area were served with two 600-pair backbone cables and the (sub) feeder cable
12 was 900-pair, the SAI would need a capacity of at least 2,100 pairs (2 x 600 +
13 900). However, the formulas used in HM 5.3 Revised do not insure that the
14 required SAI capacity is provided.

Deleted: HM 5.3

15 For example, consider Cluster 2 in the ACME wire center. The relevant
16 characteristics are as follows:

17 Total lines: 397

18 Total Households: 265

19 Total non-residential lines:¹⁰⁴ 61

20 Calculated distribution fill: 49.6%

(...continued)

¹⁰³ Before the California Public Utilities Commission, Docket R.93-04-003/I.93-04-002, *Workshop Transcripts* (Jan. 15, 2004) at p. 3639.

¹⁰⁴ In sizing the SAI, HM 5.3 Revised counts each business, voice-grade dedicated circuit, ISDN, and dedicated ASDL line as one line, and each DS-1 as two non-residential lines.

Deleted: HM 5.3

1 Feeder sizing factor: 80%

2 HM 5.3 Revised produces the required SAI line capacity by multiplying the
3 number of households by 3.5 and the number of non-residential lines by 2 (i.e.,
4 $3.5 \times 265 + 2 \times 61 = 989$). HM 5.3 Revised then utilizes the next largest SAI
5 size of 1,200.

6 The calculated distribution fill implies that 800 lines terminate at the SAI
7 on the distribution side (397/0.496). Applying the 80 percent feeder-sizing
8 factor produces a required capacity of 497 lines, which requires a 600-pair
9 feeder cable. Thus, there would be an SAI capacity shortfall of 200 lines in this
10 example (800 + 600 – 1,200).

11 The situation illustrated by this example is very common: 551 of the 829
12 main clusters produced by the Model have SAIs that are too small to handle the
13 distribution and feeder cables that are supposed to meet at the SAI.
14 Importantly, these clusters account for over 1.02 million of the approximately
15 1.06 million lines modeled by HM 5.3 Revised.

16 **Q. IS THERE ANOTHER WAY TO ILLUSTRATE THE INADEQUATE SAI**
17 **CAPACITY?**

18 **A.** Yes. HM 5.3 Revised's achieved fills are approximately 50 percent for
19 distribution and 80 percent for feeder. Putting aside the insufficiency of such
20 fills, the fact is, the capacity implied by these figures is only available if all of the
21 pairs can terminate at the SAI. In particular, the SAI must have space for about
22 2 connections at the distribution side (1/0.5) and 1.25 at the feeder side (1/0.8),
23 or about 3.25 overall. Therefore, the total SAI capacity required to

1 accommodate Verizon NW's 1.06 million lines is about 3.5 million connections.

2 HM 5.3 Revised in contrast, provides only 2.6 million connections.

Deleted: HM 5.3

3 **Q. CAN A USER CHANGE AN INPUT TO PROVIDE MORE SAI CAPACITY?**¹⁰⁵

4 **A.** No. There are no inputs that allow the user to adjust SAI capacities.

5 Accordingly, the under-sizing of SAIs cannot be fixed short of changing specific

6 formulas in HM 5.3 Revised. Consequently, the reported achieved distribution

7 and feeder fills, which are themselves unrealistically high, cannot be realized

8 because all pairs cannot be connected at the SAI.

Deleted: HM 5.3

9 **Q. ARE THERE PARTICULARLY EXTREME EXAMPLES OF INADEQUATE SAI**
10 **CAPACITY?**

11 **A.** Yes. HM 5.3 Revised assumes that 8 clusters are "high-rise" buildings, which

12 range in size from a "building" of 62 floors in the Everett (XC) wire center¹⁰⁶ to a

13 "high rise" of a single story.¹⁰⁷ For these clusters, HM 5.3 Revised assumes

14 that there is an indoor SAI in the basement of a building and riser cables within

15 the building. As Mr. Murphy explains in detail, HM 5.3 Revised therefore places

16 only 8 indoor SAIs throughout Verizon NW's entire territory, and, in the process,

Deleted: HM 5.3

Deleted: HM 5.3

Deleted: HM 5.3

¹⁰⁵ In the SBC California UNE proceeding, ALJ Duda requested a table that contained, among other items, the achieved SAI fill. This request required special calculations with HM 5.3 Revised's intermediate output, similar to my analysis here. For that exercise, AT&T/MCI defined the SAI fill as the ratio of twice the number of lines to total SAI capacity. This definition would produce an astounding 83 percent fill for Verizon NW.

Deleted: HM 5.3

¹⁰⁶ Notably, the New Jersey Board cited the HAI Model's anomalous treatment of high-rise buildings (i.e., its erroneous representation of extremely tall buildings) as one of its main reasons for rejecting the model. New Jersey Order at p. 25.

¹⁰⁷ HM 5.3 Revised estimates the size of a high-rise building by first assuming its footprint is 8,000 square feet. It next estimates the required floor space by assuming that each household requires 1,500 square feet and each employee requires 200 square feet. The required floor space is then divided by the building's footprint to estimate the number of stories. Model Description at p. 34.

Deleted: HM 5.3

1 reduces costs by substituting low-cost aerial distribution structures for costly
2 underground feeder facilities in high density areas.

3 Further, in all such buildings, the indoor SAIs are too small to
4 accommodate the feeder and riser cable that need to be joined. The most
5 extreme example is the “high-rise” building in Everett (XC) of one story. It is
6 equipped with a 50-line SAI (typically sufficient for under 20 working lines), yet
7 contains 551 lines.

8 3. STRAND-DISTANCE CONSTRAINT

9 **Q. WHAT PROBLEMS, IF ANY, HAVE YOU AND VERIZON NW’S OTHER**
10 **WITNESSES ENCOUNTERED WITH HM 5.3 REVISED’S STRAND**
11 **DISTANCE CONSTRAINT?**

Deleted: HM 5.3

12 **A.** As Mr. Dippon describes, in low-density areas, a fundamental problem arises
13 when irregularly shaped clusters formed in TNS’s preprocessing stage are
14 converted into rectangles of the same area for use in HM 5.3 Revised’s
15 distribution module. The FCC recognized this, finding that:

Deleted: HM 5.3

16 HAI’s approach of designing plant to simplified customer
17 locations within rectangularized serving areas, instead of to
18 actual customer locations, could result in a systematic
19 underestimation of outside plant costs ... The HAI Model
20 also sacrifices accuracy by assuming that customers are
21 dispersed uniformly within its distribution areas ... We
22 agree that inaccuracies may be introduced by modifying
23 the geographical boundaries of distribution areas and the
24 location of customers within those areas for purposes of
25 constructing outside plant.¹⁰⁸

¹⁰⁸ Fifth Report and Order, *In re Federal-State Joint Board on Universal Service, In re Forward-Looking Cost Mechanism for High Cost Support for Non-Rural LECs*, 13 FCC Rcd 21323, ¶¶ 57-58 (1998) (“Fifth Report and Order”).

1 The Florida Commission reached an almost identical conclusion:

2HAI has certain defects and we cannot recommend
3 reliance on its cost estimates. While the HAI Model starts
4 out with data on actual customer locations, *it disregards*
5 *much meaningful information and chooses not to build*
6 *plant to any of these known sites.* Instead, for modeling
7 convenience, what began as irregular polygons reflecting
8 natural customer groupings were transformed into regular
9 rectangles. Unfortunately, this step appears to have
10 introduced a downward bias into the model.¹⁰⁹

11 Despite the fact that the Model's proponents seem to have been
12 ambivalent on the use of the strand distance,¹¹⁰ to address this problem, the
13 Model now includes an option that adjusts the distribution distance to the strand
14 distance (a form of "minimum spanning tree" ("MST") distance).¹¹¹ In addition,
15 although the option was introduced to address regulators' concerns about
16 *insufficient* facilities in low-density areas (thus producing costs that are too low),
17 using the option has typically *reduced the estimated costs* in higher density
18 areas. However, for Verizon NW, the constraint increases both total route
19 distance (from 83.8 million to 94.5 million feet) and the resulting estimated loop

¹⁰⁹ Before the Florida Public Service Commission, Docket No. 980696-TP, *Final Order Providing Definition of Basic Local Telecommunications Service and Closing Docket* (Jan. 7, 1999) at pp. 11-12 (emphasis added).

¹¹⁰ In earlier versions of the HAI Model, its proponents expressed strong reservations about the usefulness of the strand distance adjustment: "Setting the switch 'off' would be consistent with the HAI Model developers' strong reservations about the usefulness of the MST [minimum spanning tree] as an indicator of what the DRD [distribution route distance] should be." Before the Massachusetts Department of Telecommunications and Energy, D.T.E. 01-20, *Direct Testimony of Robert A. Mercer on behalf of AT&T* (May 8, 2001) at RAM-3 (HAI Model Release 5.2a-MA Inputs Portfolio) at Section 2.13.1, p. 47. This qualification has been removed from the current version of the HM 5.3 Revised Inputs Portfolio.

Deleted: HM 5.3

¹¹¹ The MST distance is a construct from graph theory. A spanning tree is a set of line segments that connect every point in a dispersion of points, simply drawing a line from one point to another. Dr. Mercer reports that these lines are based on right-angle routing. The MST for a set of points is the set of connecting line segments whose total length is the shortest possible for the given set of points.

(continued...)

1 cost (from \$8.18 to ~~\$8.50~~). More importantly, if anything, ~~HM 5.3 Revised's~~ use
2 of the strand distance makes the distribution clusters less representative of the
3 areas in which Verizon NW's actual customers live.

4 **Q. WHAT OTHER PROBLEMS ARE ASSOCIATED WITH THE MODEL'S USE**
5 **OF THE MST ADJUSTMENT?**

6 **A.** The Model's MST adjustment only serves to further distort the clusters modeled

7 by ~~HM 5.3 Revised~~. ~~HM 5.3 Revised's~~ distribution module calculates the ratio

8 of the unadjusted distribution distance produced by the Model to the MST
9 distance. All distribution distances (e.g., cable lengths and associated support
10 structure distances) are scaled by this ratio. The associated investment and
11 expenses for distribution plant are then based on these scaled distances. As a
12 result, the MST adjustment distorts all of the clusters (and implicitly the

13 customer locations within the clusters) modeled by ~~HM 5.3 Revised~~ -- a fact that

14 only exacerbates the clusters' distortion of actual customer locations identified
15 by Mr. Dippon and recognized by the FCC and the Florida Commission. For
16 example, when the MST adjustment calls for less cable than the Model would
17 have provided absent the adjustment, the rectangular clusters are compressed
18 along both dimensions. In the process, customers are in effect packed into
19 smaller, higher density lots. Conversely, when the strand distance exceeds the
20 calculated route distance, the cluster in effect expands and potentially overlaps

(...continued)

The MST distance is a measure of the dispersion of a set of points, and is provided in the cluster database by TNS.

1 with adjoining clusters. Mr. Dippon provides maps that illustrate these
2 phenomena.

3 **Q. IS HM 5.3 REVISED'S EXPANSION AND COMPRESSION OF**
4 **DISTRIBUTION FACILITIES THROUGH THE STRAND DISTANCE**
5 **ADJUSTMENT A REASONABLE APPROXIMATION OF HOW FACILITIES**
6 **ARE PLACED WITHIN DISTRIBUTION AREAS?**

Deleted: HM 5.3

7 **A.** No. Unlike the abstract “grill,” which then is scaled up or down to match TNS’s
8 strand distance, in the real world, cables are routed, and the specific sizes of
9 the cables linking the distribution terminals to the SAI are chosen to fit the
10 unaltered layout of a distribution area. HM 5.3 Revised's modeling techniques
11 thus represent a significant break from reality. As Mr. Dippon describes in
12 detail, while the TNS clustering process results in clusters with irregular areas,
13 HM 5.3 Revised (1) distorts these areas into rectangles; (2) essentially
14 assumes that locations are evenly distributed over the rectangles; (3) builds a
15 specific grid of backbone and branch cables to fill the rectangle;¹¹² and (4) at
16 the end of the process, attempts to impose a semblance of realism by forcing
17 the total length of the grid to match TNS’s strand distance measure. In the
18 process, the Model either shrinks or expands the entire grid (cable sizes and
19 all), with no regard as to how the locations originally included in the cluster
20 could actually be connected.

Deleted: HM 5.3

Deleted: HM 5.3

¹¹² At this stage of the process, distribution cables run one lot length or width short of the edges of the rectangle.

1 In contrast, VzLoop produces a much more realistic representation of
2 these routes than does HM 5.3 Revised's abstract "grills."¹¹³ Verizon's cost
3 model starts with the actual locations of the distribution terminals and the
4 specific SAIs to which those terminals are assigned. It then designs plant to
5 these locations without any distortions (e.g., it does not assume that customers
6 are evenly dispersed over perfect rectangles, as HM 5.3 Revised does).
7 Further, unlike HM 5.3 Revised, VzLoop has specific information on the type of
8 structure (e.g., buried or underground) that would be used to connect locations
9 within distributions areas, thereby producing a much more realistic depiction of
10 Verizon NW's forward-looking network.

11 **Q. ARE THERE ANY SPECIFIC PROBLEMS CAUSED BY HM 5.3 REVISED'S**
12 **EXPANSION AND COMPRESSION OF DISTRIBUTION FACILITIES**
13 **THROUGH THE STRAND DISTANCE ADJUSTMENT?**

14 **A.** Yes. Mr. Murphy identified numerous instances where HM 5.3 Revised
15 produces copper loop distances that exceed the purported maximum threshold.
16 This error arises from the fact that, while HM 5.3 Revised is designed to prevent

¹¹³ HM 5.3 Revised's proponents frequently assert that the Model's representation of distribution areas reasonably approximates how the FCC's Synthesis Model treats distribution areas. Bryant Direct Testimony at p. 16. This is false. In fact, VzLoop comes much closer to what the FCC's Synthesis Model intends to accomplish than does HM 5.3 Revised. VzLoop and the Synthesis Model both start with measurements of where distribution terminals are located and where those terminals are assigned to specific SAIs. Both models then design plant to these locations without any distortions (e.g., assuming that customers are evenly dispersed over perfect rectangles, as HM 5.3 Revised does). In fact, viewed in this light, VzCost is an improvement over the FCC's approach in a number of ways: (1) it has better and more up-to-date information on where distribution terminals are located (the Synthesis Model, at best, only approximates such locations through its use of surrogate customer locations that are several years old); (2) the assignment of terminals to SAIs reflects real-world engineering and design considerations, rather than the workings of an abstract clustering algorithm; and (3) VzLoop has specific information on the type of structure (e.g., buried or underground) that would be used to connect locations within distributions areas.

1 such occurrences, the requisite safeguards are only invoked *before* distances
2 are scaled by the strand distance. For example, when the dimensions of a
3 rectangular cluster would produce excessively long copper lengths, HM 5.3
4 Revised divides such clusters into two or four smaller clusters. In effect,
5 clusters that “pass” such tests before the strand distance adjustment applies
6 now “fail” the tests subsequent to the adjustment. As a result, the network
7 facilities designed by HM 5.3 Revised are faulty from an engineering
8 perspective.¹¹⁴ In short, the expansion induced by the strand distance
9 adjustment seriously distort not only the outputs of the Model, but also the
10 engineering rules the Model was intended to represent.¹¹⁵

Deleted: HM 5.3

Deleted: HM 5.3

Deleted: By the same token, the compression of other clusters means that some clusters that are deemed to require DLC equipment prior to applying the strand distance adjustment would qualify for all-copper treatment afterwards (e.g., the maximum loop length in the cluster would be less than the threshold). In fact, clusters whose loop lengths are under the relevant thresholds for the provision of DLC (and do not have outliers attached) account for about 12 percent of Verizon NW’s lines.

Deleted: and compression

Deleted: HM 5.3

Deleted: HM 5.3

¹¹⁴ Although HM 5.3 Revised deploys DLC facilities in instances where copper lengths are excessive, this does not remedy the problem – copper distribution lengths can still exceed the maximum.

¹¹⁵ A similar flaw in the workings of the strand distance adjustment is illustrated by changing the distribution module (Column Q) so that the number of locations to which the Model builds loop plant matches the number of locations in the TNS database. As Mr. Dippon explains, HM 5.3 Revised compresses locations determined by TNS into a smaller number of “lots,” which would intuitively seem to produce lower costs, because the effect of increasing lots would seem to be an increase in both the lengths of backbone and branch cables (because the decrease in lot size that accompanies the increase in the number of lots brings cables closer to the edge of the rectangular clusters) and a possible increase in the number of branches (smaller lots may mean that more “roads” are needed). In fact, the opposite is true – increasing the number of lots results in a decrease in loop cost from \$8.50 to \$8.37. And increasing the number of lots causes a decrease in the number of DLC (fiber-fed) lines, as well as decreases in the distribution and DLC investments per line, which are partially offset by an increase in feeder investment.

Deleted: 7.64

Deleted: 7.53

These anomalous results are a consequence of the strand distance constraint. When more branches are needed, the proportion of distance accounted for by the typically smaller (in terms of number of pairs) branch cables increases. Therefore, the average cable cost per unit of distance decreases. And, because the strand-distance constraint causes the total distribution distance to be the same in the two scenarios, cable costs are lower when there are more lots.

The explanation for the decrease in DLC lines (and the concomitant decrease in DLC investment per line) is somewhat similar. The increase in the number of branches (as well as the increased length of branch and backbone cables before the strand distance constraint is imposed) means that the multiplier that either expands or shrinks the “grill” is smaller when there are more lots. This, in turn, reduces the maximum distance from the SAI. Therefore, there are clusters for which the maximum copper length is exceeded (and therefore fiber feeder is deployed) when the default number of lots is used, but the maximum distance is not exceeded and copper feeder is deployed when there are more lots (because the “grill” is smaller in area). The increase in feeder costs in these cases results from the fact that for a given number of loops, fiber cable is cheaper than copper cable.

1 **4. INTEROFFICE FACILITIES**

2 **Q. PLEASE DESCRIBE HM 5.3 REVISED'S APPROACH TO MODELING**
3 **INTEROFFICE FACILITIES.**

Deleted: HM 5.3

4 **A. HM 5.3 Revised** produces unit costs for interoffice transport UNEs based on its
5 representation of the network components that link Verizon NW's end-office
6 switches to each other, to tandem switches, and to interexchange carriers'
7 ("IXC") points-of-presence ("POPs"). The Model depicts 13 ring systems, one
8 for each of the tandems (or pseudo tandems) modeled by HM 5.3 Revised.¹¹⁶
9 Each of these ring systems actually consists of several rings that are linked
10 together, either because the tandem is part of multiple rings or by intrabuilding
11 fiber links that join the remaining rings in the system. These rings can contain
12 up to 16 nodes.¹¹⁷

Deleted: HM 5.3

Deleted: HM 5.3

13 HM 5.3 Revised purportedly designs "optimal" interoffice routes, which
14 are the product of a 35-page, undocumented Visual Basic program that
15 supposedly is able to find the "least cost" configuration of interoffice rings.¹¹⁸ As
16 Mr. Murphy explains, the demand information used to determine these rings, as
17 well as the engineering assumptions employed therein, are severely flawed.¹¹⁹

Deleted: HM 5.3

18 **Q. WHAT FLAWS HAVE YOU IDENTIFIED REGARDING HM 5.3 REVISED'S**
19 **APPROACH TO MODELING INTEROFFICE FACILITIES?**

Deleted: HM 5.3

¹¹⁶ The Model considers the following wire centers as the tandem locations for the 13 ring systems: Blaine, Everett, Grayland, Kirkland, Mount Vernon, Naches, Palouse, Rockford, North Richland, Skykomish, Seattle, and Wenatchee.

¹¹⁷ The Model produces a total of 22 rings for the 99 wire centers modeled by HM 5.3 Revised.

Deleted: HM 5.3

1 A. Even if HM 5.3 Revised's approach to modeling interoffice facilities did not
2 suffer from the flaws Mr. Murphy identifies, it is far from clear that the
3 undocumented program is producing meaningful results. The program
4 purportedly decides which wire centers belong on which rings using an overly
5 simplified sequential comparison of the cost of directly connecting an office to a
6 tandem with the cost of adding it to a ring. The costs considered in this
7 comparison depend on the input costs for fiber cable, support structure, and
8 electronics. In fact, HM 5.3 Revised's method of determining "optimal"
9 interoffice SONET rings is very insensitive to the both the demand that it
10 considers (i.e., traffic volumes entering or exiting a ring at each wire center) and
11 the costs for fiber cable and electronics -- a result that calls into serious
12 question what exactly is being "optimized."

Deleted: HM 5.3

13 For example, I tested the impact on interoffice design of removing the
14 effect of high-capacity loops, and concluded that they account for about two-
15 thirds of the demand HM 5.3 Revised assumes in designing and costing
16 interoffice rings. As one would expect, this demand is not uniformly distributed.
17 Rather, some of the smaller offices have little to no interoffice demand
18 associated with high-capacity loops (and therefore, their interoffice demand with
19 or without high-capacity loops are similar), while other offices have large
20 numbers of high-capacity loops. Consequently, both HM 5.3 Revised's total

Deleted: HM 5.3

Deleted: HM 5.3

(...continued)

¹¹⁸ Dr. Mercer provides a high-level description of what the program purportedly does. See Mercer Supplemental Direct Testimony at RAM-4 (HM 5.3 Model Description) at pp. 66-71.

¹¹⁹ Murphy Reply Testimony at Section V.

Deleted: HM 5.3

Deleted: HM 5.3

Deleted: HM 5.3

1 interoffice demand and the distribution of that demand among individual wire
2 centers are radically different when high-capacity loops are excluded. Despite
3 the fact that such a change would seem to call for a different arrangement of
4 “optimal” SONET rings, *HM 5.3 Revised produces absolutely identical rings,*
5 *regardless of whether high-capacity loops are present or not.*¹²⁰

6 **Q. WHAT ARE THE COST CONSEQUENCES OF THE MODEL’S**
7 **INSENSITIVITY TO MANY ASPECTS OF RING DESIGN?**

8 **A.** The extreme sensitivity of the unit costs of interoffice facilities, which Mr.
9 Murphy has identified, is the result of: (1) the insensitivity of total ring costs to
10 demand; and (2) the concomitant high sensitivity of total demand to the
11 essentially arbitrary input that includes from zero to 100 percent of non-
12 switched demand when determining interoffice investments. The following table
13 illustrates this phenomenon.

14 **TABLE 9**

	0%	50%	100%
--	----	-----	------

¹²⁰ In contrast to the dubious nature of the interoffice facilities’ locations produced by *HM 5.3 Revised*, in a proceeding before the FCC, Stephen Turner, a witness representing AT&T/MCI, agreed that Verizon’s model is capable of producing reasonable results:

Mr. [Francis J.] Murphy, at least in his testimony, goes at length in talking about how difficult it is to model a SONET network, and Mr. Gansert [Verizon’s engineering witness] was saying he thought I was initially agreeing with him, and I would say it’s a very complex problem to do. That said, though, given that, I think you have to look at what is Verizon’s current experience is in terms of trying to evaluate, at least in this area because of the complexity, the number of nodes that they have on their SONET ... I mean, what Verizon has actually implemented in their network is rational implementation for SONET traffic given the constraints that they have.

Before the Federal Communications Commission, CC Docket Nos. 00-218, -249, -251, *Hearing Transcript* (Nov. 29, 2001) at pp. 5630-32. Indeed, the FCC’s Wireline Competition Bureau adopted Verizon’s transport model instead of the model proffered by AT&T/MCI (which is substantially similar to *HM 5.3 Revised*’s module). See Virginia Arbitration Order at ¶¶ 503-08.

Total Investment	\$120 Million	\$152 Million	\$184 Million
# of DS-3s	301	944	1,584
Investment/DS-3	\$397 Thousand	\$162 Thousand	\$116 Thousand

1
2 The table shows that changing the user-adjustable input “fraction of high-
3 capacity loops requiring interoffice transport” from 0 percent to 50 percent
4 (default) to 100 percent causes a large difference in demand (measured in DS-
5 3s), but only a modest difference in cost. Indeed, changing this input from the
6 value of 100 percent that was assumed in previous versions of HM 5.3 causes
7 a large increase in unit investment (from \$116 thousand to \$162 thousand).

Deleted: HM 5.3

8 **Q. DOES HM 5.3 REVISED'S APPROACH TO MODELING INTEROFFICE**
9 **FACILITIES PRODUCE MEANINGFUL RESULTS?**

10 **A.** No. Given that the Model essentially guesses at the volume of demand that
11 interoffice facilities need to accommodate (by invoking the input illustrated in
12 Table 9), and the fact that the resulting investment is extremely insensitive to
13 that arbitrary demand, the Model cannot be expected to produce meaningful
14 results. Indeed, the shaky foundations of HM 5.3 Revised's interoffice
15 calculations produce results that defy common sense. In particular, despite the
16 expectation that high-capacity facilities such as DS-3s would be less costly on
17 interoffice facilities than as stand-alone loops to end-user customers, because
18 of the greater economies of scale in the former, HM 5.3 Revised produces
19 higher costs for interoffice DS-3 facilities than it does for stand-alone loops. For
20 the interoffice DS-3 facilities, the total cost is \$3,065, with about \$2,590
21 attributable to electronics and about \$475 to transmission facilities (i.e., fiber

Deleted: HM 5.3

Deleted: HM 5.3

1 cables and support structures). For DS-3 loops to end-users, the total cost is
2 about \$653, with \$574 attributable to electronics and about \$80 to transmission
3 facilities.¹²¹

4 These anomalous results are not surprising, and indeed are consistent
5 with the erroneous results produced by previous versions of the HAI Model. In
6 fact, while some version of the HAI Model's switching and interoffice module
7 has been available since 1998, getting it to produce the proper amounts of
8 interoffice facilities has been a particularly vexing problem. The seriousness of
9 the problem first became apparent in the New York UNE proceeding. Verizon's
10 panel explained that the HAI Model failed to properly include substantial
11 amounts of interoffice equipment, thereby causing AT&T/WorldCom to submit
12 two corrected versions of the switching and interoffice module during the course
13 of the proceeding.¹²² After the New York proceeding, the module was modified
14 at least once (e.g., the module included in HM 5.2a and filed in 2001 in a
15 Massachusetts proceeding differed from the version filed in New York). In the
16 ongoing SBC California UNE proceeding, I uncovered additional errors in HM

¹²¹ Mr. Murphy has identified some serious design flaws associated with HM 5.3 Revised's assumptions regarding the engineering of DS-3 loops, which ultimately result in DS-3 loops that would be nonfunctional in the real world.

¹²² The inclusion of improperly excluded equipment would obviously increase total investment. AT&T/WorldCom reduced the impact of the greater amounts of equipment by simultaneously changing the input prices for interoffice electronic components. In ultimately rejecting the Model, the New York Commission appeared to take notice of such corrections: "But when all is said and done, the recurring corrections to the Model seem to confirm its weaknesses more than its suppleness, and the Model continues to suffer from the flaws identified by the Commission in the First Elements Proceeding." Before the New York Public Service Commission, Case 98-C-1357, *Recommended Decision on Module 3 Issues by Administrative Law Judge Joel A. Linsider*(May 16, 2001) at p. 34 ("Linsider Decision").

1 5.3's interoffice calculations, which AT&T/MCI subsequently acknowledged.¹²³
2 Correction of these errors increased interoffice electronics investments by at
3 least 50 percent.¹²⁴

4 5. END-OFFICE SWITCHING

5 **Q. DOES HM 5.3 REVISED'S SWITCHING COST FUNCTION ESTIMATE THE**
6 **APPROPRIATE, FORWARD-LOOKING SWITCHING INVESTMENT?**

Deleted: HM 5.3

7 **A.** No, it does not. HM 5.3 Revised's estimate of new switch costs assumes only
8 new switches. Verizon NW's actual forward-looking costs, however, will be
9 largely for upgrades and growth additions.

Deleted: HM 5.3

10 **Q. IS THE EXCLUSION OF THE COSTS OF UPGRADES AND GROWTH**
11 **SWITCH ADDITIONS FROM HM 5.3 REVISED SIGNIFICANT?**

Deleted: HM 5.3

12 **A.** Most definitely. Earlier versions of the HAI Model relied upon a 1995 McGraw-
13 Hill study, which indicated that add-on switch prices were about 50% higher
14 than new switch prices. The study explained that:

15 Once a switch supplier sells a new system, it has a nearly captive
16 customer; a telecommunications company can only grow a switch
17 by buying add-on lines from the manufacturer of a switch.
18 Therefore, add-on lines are priced higher than lines on new
19 systems and represent higher marginal sales.¹²⁵

20 The McGraw-Hill Study showed that carriers actually spend about three times
21 more to purchase additions to existing switches than to purchase new switches,

¹²³ Before the California Public Utilities Commission, Application Nos. 01-02-024 et al., *Declaration of Robert A. Mercer in support of Joint Applicants' Rebuttal Comments*. (March 12, 2003) at pp. 105-07.

¹²⁴ The counterintuitive results described in the last paragraph indicate that merely correcting calculation errors is not sufficient to render HM 5.3 Revised's interoffice facilities' calculations reasonable.

Deleted: HM 5.3

1 and noted that the “gap between additions and new installations will continue to
2 increase as the installed base approaches 100% digitization.”¹²⁶ As the 1995
3 study anticipated, Verizon NW’s forward-looking switch costs will be largely the
4 cost of upgrades and growth switch additions -- Verizon NW has no plans of
5 installing new local switches because it has achieved “100% digitization.” Yet,
6 HM 5.3 Revised assumes away all costs of upgrades and growth switch
7 additions.

Deleted: HM 5.3

8 **Q. ARE HM 5.3 REVISED’S INPUT ASSUMPTIONS CONSISTENT WITH**
9 **RESPECT TO SWITCHING COSTS?**

Deleted: HM 5.3

10 **A.** No. If the Commission wants to accept HM 5.3 Revised’s approach, and
11 assume that there is never any growth switching added or upgrades, it would
12 need to revise a number of HM 5.3 Revised’s input assumptions in ways that
13 would increase greatly the Model’s cost estimates. For example, if Verizon NW
14 actually installed switches with no plans to ever purchase additional lines, which
15 is not realistic, then the switches would need substantial excess capacity --
16 much higher than assumed by HM 5.3 Revised. For example, if lines were
17 growing at 3 percent annually, and 6 percent capacity is needed for
18 administrative fill, installing a switch with enough capacity for the 16-year life
19 assumed by HM 5.3 Revised would require 70 percent initial spare capacity.
20 Because spare capacity would be substantially increased (on the order of 30

Deleted: HM 5.3

¹²⁵ Northern Business Information, *US Central Office Equipment Market – 1995*, McGraw-Hill.

¹²⁶ *Id.* at p. 61.

1 percent over the life of the switch), the initial investment and capital costs would
2 also increase.

3 **Q. ARE THERE ALTERNATIVE MODIFICATIONS THAT COULD**
4 **ACCOMMODATE HM 5.3 REVISED'S UNREALISTIC SWITCHING**
5 **ASSUMPTIONS?**

6 **A.** Yes. Consistent with HM 5.3 Revised's assumption that the network uses only
7 new equipment, each switch would have to be replaced every few years to
8 allow for growth and technological advances in switching (e.g., GR-303
9 interfaces). Accordingly, the depreciation on switches would have to be much
10 higher because the life of the switch would be substantially shorter than
11 assumed by HM 5.3 Revised. This would obviously increase the initial
12 investment and the subsequent capital costs by significant amounts. Replacing
13 a switch every 3 years, rather than every 16 years, implies that depreciation is
14 more than 5 times higher per year. This also increases annual switch costs by
15 substantial amounts -- the annual charge factor for a 3-year life is about 3.3
16 times the corresponding factor for a 16-year life.

Deleted: HM 5.3

Deleted: HM 5.3

Deleted: HM 5.3

17 The only other alternative, under HM 5.3 Revised's assumption that
18 growth switch costs are never incurred, would be to install a new, smaller switch
19 every time Verizon NW experienced enough growth to exhaust existing switch
20 capacity. At a growth rate of about 3 percent per year, a switch initially installed
21 at HM 5.3 Revised's assumed utilization would need to be augmented with a
22 new, smaller switch at the same location in about 3 years. Adding new
23 switches every 3 years to serve line growth and maintain an assumed

Deleted: HM 5.3

1 administrative fill of 94 percent would also increase the cost per-line
2 substantially, even using the seriously understated costs for new switches in

3 HM 5.3 Revised

Deleted: HM 5.3

4 Of course, the need for floor space, the costs for interconnections
5 between the additional switches, as well as the costs of disrupting the central
6 office, should also be included. In addition, HM 5.3 Revised's inputs are
7 inappropriate because, if Verizon NW only deployed new switches and never
8 added growth lines, the manufacturers' discounts would be much smaller (and
9 thus prices would be higher) for new lines. If switch manufacturers could not
10 count on the higher margins they currently receive for growth lines, they would
11 be unwilling to accept the low margins currently earned on initial installations.

Deleted: HM 5.3

12 **Q. DOES HM 5.3 REVISED INCORPORATE THE FCC'S SWITCH COST**
13 **COMPUTATION?¹²⁷**

Deleted: HM 5.3

14 **A.** No. HM 5.3 Revised reduces switching costs when DLC lines are deployed; the
15 FCC's Synthesis Model does not. The result is a reduction in end-office
16 switching investment by about 13 percent.

Deleted: HM 5.3

17 **VIII. EXPENSES**

18 **Q. PLEASE DESCRIBE HM 5.3 REVISED'S EXPENSE MODULE.**

Deleted: HM 5.3

19 **A.** As previously discussed, the assorted components of HM 5.3 Revised estimate
20 the investment required for various network facilities (e.g., the cable and wire

Deleted: HM 5.3

¹²⁷ Indeed, the FCC's Wireline Competition Bureau selected Verizon's SCIS model over the switching model used in the HAI Model, citing SCIS's superior treatment of discounts offered by vendors and the fact that the data used to estimate switch investments (which HM 5.3 Revised has adopted in this proceeding) are dated. See Virginia Arbitration Order at ¶¶ 367-73.

Deleted: HM 5.3

1 needed for loop facilities, the number and type of switches to be modeled, and
2 the amount of electronics needed for fiber optic facilities). And, as described
3 more fully below, the Model also produces estimates of: (1) investments for
4 support assets, such as buildings and motor vehicles, (2) annual capital costs
5 associated with network and support investments, (3) annual operating and
6 maintenance expenses for the network and support facilities, and (4) annual
7 network operations and corporate overhead expenses.

8 Cost estimates for each of these four categories start with the
9 investments in network facilities produced by HM 5.3 Revised (i.e., they are all
10 multiples of the network investment levels). For example, general support
11 investments apply the ratio of the ARMIS (booked) investment -- a particular
12 general support category (e.g., buildings not used for switches) -- to investment
13 in ARMIS total plant in service ("TPIS"), less general support investment. Thus,
14 if building investment is five percent of TPIS in the ARMIS data, HM 5.3
15 Revised assumes that building investment would be the same five percent of
16 the investment in network facilities produced by the Model.¹²⁸ Because HM 5.3
17 Revised produces substantially less investment than Verizon NW's book
18 investment, it in effect assumes that an "efficient carrier" could serve the same

Deleted: HM 5.3

Deleted: HM 5.3

Deleted: HM 5.3

¹²⁸ HM 5.3 Revised assumes that a portion of support assets are assigned to retail services (and therefore are not included in UNE costs). For buildings, furniture, office equipment, and general purpose computers, the Model first assigns corporate operations expenses to wholesale and retail, based on the proportion of total expenses for plant (less general support), network operations, and customer operations (ARMIS Report/Account 6600) that are in the customer operations account. HM 5.3 Revised then calculates an allocator for general support costs that is the ratio of the sum of network operations expenses and the corporate operations expenses assigned to wholesale, to the sum of network operations, customer operations, and corporate operations. That calculation results in an allocation of about 42 percent of these assets to wholesale. A somewhat different calculation results in an allocator of about 41 percent for motor vehicles and work equipment.

Deleted: HM 5.3

Deleted: HM 5.3

1 volumes of traffic Verizon NW serves today with fewer (or smaller) buildings,
2 fewer motor vehicles, less investment in computers, and so forth, as shown in
3 Tables 2A and 2B above. AT&T/MCI have produced no support for this
4 arbitrary and questionable outcome.

5 In addition, the ratio of the book investment of a support asset to the total
6 network investment should not be applied to the lower levels of forward-looking
7 investment produced by HM 5.3 Revised, because there is no basis for
8 assuming that the level of support assets varies directly with the level of
9 network investment. For example, the price of central office switches has
10 declined over time (although not as much as the HM 5.3 Revised suggests), but
11 the cost of land and buildings has not. Therefore, any land and building ratio
12 based on book cost would be too low for calculating forward-looking costs if the
13 ratio is applied to discounted, forward-looking switch investments. Such
14 erroneous assumptions underestimate the required investment in land and
15 buildings. In fact, the average ratio of support assets to network assets based
16 on current costs is 25 percent higher than the average ratio based on book
17 costs.¹²⁹

Deleted: HM 5.3

Deleted: HM 5.3

18 **Q. DOES HM 5.3 REVISED ACCURATELY ESTIMATE NETWORK**
19 **OPERATIONS EXPENSES?**

Deleted: HM 5.3

20 **A.** Absolutely not. HM 5.3 Revised's approach to estimating network operations
21 expenses (ARMIS Account 6530) is similarly flawed. HM 5.3 Revised

Deleted: HM 5.3

Deleted: HM 5.3

¹²⁹ This calculation uses the current cost to book cost ratios reported in Appendix D of the FCC's Tenth Report and Order.

1 multiplies: (1) the ratio of book expenses in this account to total current
2 investment, by (2) the total investment produced by the Model, to estimate ~~HM~~
3 ~~5.3 Revised~~'s network operations expenses. As discussed herein, because ~~HM~~
4 ~~5.3 Revised~~'s investments are understated, network operations expenses are
5 understated as well. Even if a forward-looking network required less
6 investment, there is no logical reason to assume that a reduction in these
7 investments automatically implies that an efficient firm could proportionately
8 reduce its expenditures for power, network engineering, and the like.

Deleted: HM 5.3

Deleted: HM 5.3

9 **Q. PLEASE DESCRIBE ~~HM 5.3 REVISED~~'S USE OF EXPENSE-TO-**
10 **INVESTMENT RATIOS, AND THE PROBLEMS ASSOCIATED THEREWITH.**

Deleted: HM 5.3

11 **A.** With the exception of the annual capital costs,¹³⁰ the specific factors used to
12 produce ~~HM 5.3 Revised~~'s cost estimates are adapted from the FCC Synthesis
13 Model. These factors include expense-to-investment ratios for specific plant
14 categories (e.g., aerial copper cable), and each category of support asset (e.g.,
15 buildings). In order to produce reliable estimates of forward-looking expenses,
16 such expense-to-investment factors must be developed such that they
17 represent the proper *relationship* between the forward-looking level of network
18 expense and the forward-looking level of network investment.

Deleted: HM 5.3

19 As described more fully below, a fundamental problem arises when
20 these expense-to-investment ratios are used to estimate the forward-looking

¹³⁰ The Direct and Reply Testimonies of Mr. Sovereign and Dr. Vander Weide demonstrate that AT&T/MCI's recommendations for cost of capital and depreciation produce unreasonably low UNE cost estimates.

1 expenses associated with providing UNEs in Washington. Unless there is a
2 close match between the investment levels used to develop the ratios and the
3 investment levels to which the ratios are applied in the cost studies, the
4 application of such ratios, without appropriate forward-looking adjustments,¹³¹
5 will not produce accurate UNE cost estimates.¹³²

6 **Q. PLEASE EXPLAIN WHY IT IS IMPORTANT TO ALIGN THE PRICES USED**
7 **TO CALCULATE FORWARD-LOOKING INVESTMENT AND FORWARD-**
8 **LOOKING PRICES.**

9 **A.** Adjustments to expense-to-investment ratios based on booked network
10 investment are necessary to make them appropriate for estimating forward-
11 looking expenses, as the following example illustrates. Suppose a carrier
12 installed ten new poles last year for \$500 each and paid \$5 per year to maintain
13 each pole. Further, suppose the price of a new pole this year is \$600, but still it
14 costs \$5 per year to maintain. In this example, then the current cost to book
15 cost (“CC/BC”) ratio for poles is \$600/\$500 or 6/5. Application of the CC/BC
16 ratio to the booked investment in the denominator of the ratio \$5/\$500 (.01)
17 yields a new factor of .0083. Because HM 5.3 Revised in many cases

Deleted: HM 5.3

¹³¹ For example, in the case of switching, there is a clear misalignment in HM 5.3 Revised – while the FCC’s current cost-to-book cost ratio implies that Verizon NW would need to spend 89 percent of its book investment to replace its switches, HM 5.3 Revised says the replacement could be accomplished for only 23 percent.

Deleted: HM 5.3

Deleted: HM 5.3

¹³² VzCost applies a Forward-Looking Calibration (“FLC”) factor to ensure that the investment levels of the network expense factors are properly aligned with the reduced level of forward-looking investment produced by the other parts of Verizon’s cost model. See Before the Washington Utilities and Transportation Commission, Docket No. UT-023003, *Panel Testimony of Verizon Northwest Inc. on Recurring Costs* (June 26, 2003) at pp. 150-55.

1 erroneously assumes that prices are less in the future,¹³³ applying this factor to
2 the a lower pole price of, for example, \$400 produces incorrectly low
3 maintenance expense of \$3.33 per pole.

4 A similar problem arises if HM 5.3 Revised produces an incorrect
5 estimate of the quantity of facilities required by a carrier providing
6 telecommunications services. For example, if Verizon NW's real-world
7 operations require 100 poles, but HM 5.3 Revised produces only 80 poles, the
8 assumption of the \$400 pole price would produce a hypothetical investment of
9 \$32,000 (80 x \$400), and an associated maintenance expense of \$267 (0.0083
10 x \$32,000), while the real-world maintenance cost would be \$500 (100 poles x
11 \$5 per pole as described above). In the case of plant-specific expenses, the
12 costs of maintaining the network are reduced to only 50 percent of what Verizon
13 NW spent to maintain its network in 2003.

14 Finally, there is the additional problem that the FCC's expense-to-
15 investment ratios are national averages, estimated from historical 1997 and
16 1998 data.¹³⁴ As such, the use of these ratios fails to capture Washington-
17 specific or Verizon NW-specific operating conditions.¹³⁵ The FCC used
18 aggregate data for ILECs, but explicitly acknowledged that a national average

¹³³ Pole investment is a prime example of this understatement: When the pole investment in the 2003 ARMIS data is adjusted by the current cost-to-book cost ratio and then divided by the number of poles reported in the ARMIS data, the price is three times HM 5.3 Revised's pole price. Therefore, even if HM 5.3 Revised produced the correct number of poles and an accurate network expense factor was used, the associated maintenance expenses would still be understated by two-thirds.

¹³⁴ In contrast to AT&T/MCI's ratios that are based on data that are now five to six years out-of-date, Verizon NW uses data from 2001 and makes them forward-looking through the application of inflation and productivity adjustments.

Deleted: twice

Deleted: HM 5.3

Deleted: HM 5.3

Deleted: one-half

1 was appropriate for USF purposes only.¹³⁶ Similarly, although the FCC used
2 data that was based on the prices ILECs pay for equipment, the FCC used
3 nationwide estimates of input costs to calculate the value of current investment.
4 Thus, the expense factors used by AT&T/MCI for UNE purposes fail to align
5 properly with the equipment price inputs used for their Verizon NW,
6 Washington-specific cost study.

7 **Q. DESCRIBE HM 5.3 REVISED'S APPROACH TO ESTIMATING CORPORATE**
8 **OVERHEAD EXPENSES, AND THE PROBLEMS ASSOCIATED**
9 **THEREWITH.**

10 **A.** To estimate corporate overhead expenses, HM 5.3 Revised applies an
11 overhead factor of 10.4 percent to all the other costs calculated by the Model.
12 The results of this calculation are that, while Verizon NW incurred corporate
13 expenses (USOA Accounts 6710 and 6720) of about \$88 million in 2003,¹³⁷ the
14 Model produces about one quarter of that amount (or \$22 million).

15 The large reduction from Verizon NW's current expenditures results from
16 the fact that HM 5.3 Revised applies a ratio of 10.4 percent for corporate

(...continued)

¹³⁵ Virginia Arbitration Order at ¶ 136.

¹³⁶ The FCC distinguished between the use of its Synthesis Model to support the federal USF and its use for other purposes. In a USF context, the FCC did not attempt to describe any particular company (Tenth Report and Order at ¶ 360), whereas in a UNE context, the objective is to estimate the costs an ILEC actually expects to incur.

¹³⁷ This figure is the product of 2003 ARMIS expenses and HM 5.3 Revised's estimate of the proportion of corporate expenses that correspond to the "wholesale" activities depicted by the Model.

1 expenses to all of its other substantially understated forward-looking costs.¹³⁸
2 As Table 2B shows, those estimates are well below what VerizonNW needs to
3 run its current network. And the resulting overhead cost estimates, likewise,
4 understate forward-looking overhead expenses. This illustrates the general
5 problem with expense factors -- if hypothetically the cost of all network
6 components were reduced by 50 percent, there is no reason to expect, for
7 example, that only half of the current professional workforce would be required
8 to manage that network.

9 | **IX. REGULATORY SCRUTINY AND HM 5.3 REVISED'S TREATMENT OF THE**
10 **CONCERNS VOICED BY OTHER STATE REGULATORY COMMISSIONS**

11
12 **Q. WHAT WEIGHT SHOULD BE PLACED ON DR. MERCER'S STATEMENT**
13 **THAT THE HAI MODEL HAS BENEFITED FROM CAREFUL REGULATORY**
14 **SCRUTINY?**¹³⁹

15 **A.** None. While it is accurate to state that the HAI Model has been filed in many
16 states and has been extensively reviewed, such reviews have often resulted in
17 the rejection of the model. Even though the HAI Model sponsors replaced the
18 CBGs used in Release 3.1 with the cluster inputs developed by TNS (or its
19 predecessor firm), regulators in North Carolina, New Hampshire, Rhode Island,
20 New York, New Jersey, and Massachusetts have all found that the versions of

¹³⁸ VzCost applies a 4.8% Marketing factor, a 3.6% Marketing Support factor, and a 6.3% Common factor to recover overhead expenses.

¹³⁹ Mercer Supplemental Direct Testimony at pp. 6-7.

1 the HAI Model sponsored by AT&T/MCI are problematic nevertheless, and have
2 adopted the ILECs' cost models instead.¹⁴⁰

3 For example, a Recommended Decision released by the New York
4 Public Service Commission selected Verizon's cost model over the HAI Model,
5 Release 5.2 , describing the latter as "a ponderous tool that is too far removed
6 from the reality of Verizon's circumstances to be used when there is an
7 alternative better grounded in real data."¹⁴¹ Similarly, in adopting Verizon's cost
8 model, the New Jersey Board concurred with Verizon NJ and others that the
9 HAI Model "failed to use TELRIC-compliant inputs."¹⁴² Chief among the New
10 Jersey Board's concerns was "the substantial nature of the difference between
11 the [HAI Model's] cost estimates and Verizon NJ's actual experience," which
12 suggested that the HAI Model "may potentially understate forward-looking
13 costs."¹⁴³ Moreover, the New Jersey Board was troubled by AT&T's offsetting
14 adjustments and "alarmed" by the anomalous results produced by the HAI
15 Model's clustering algorithm.¹⁴⁴ In the end, the New Jersey Board declined to
16 adopt the HAI Model, noting that the "Model employs a methodology designed

¹⁴⁰ I appeared as a witness in each of these proceedings, as well as in several universal service proceedings in 1998. With the exception of Kentucky, which selected HM 5.0a for universal service purposes, the regulators in each of these states rejected the HAI Model and opted instead for the cost models sponsored by the ILECs.

¹⁴¹ Linsider Decision at p. 35. Judge Linsider's decision was subsequently affirmed by the New York Commission, which noted that "none of [the parties, including AT&T] excepts to the Judge's rejection of the HAI Model." Before the New York Public Service Commission, Case 98-C-1357, *Order on Unbundled Network Element Rates* (Jan. 28, 2002) at pp. 14-15, 17.

¹⁴² New Jersey Order at p. 25.

¹⁴³ New Jersey Order at pp. 25-26.

¹⁴⁴ New Jersey Order at p. 26.

1 to create a least-cost, most efficient network without regard to realistic design
2 considerations.¹⁴⁵

3 **Q. HAVE ALL OF THE PROBLEMS IDENTIFIED BY THE COMMISSION WITH**
4 **RESPECT TO PREVIOUS VERSIONS OF THE HAI MODEL BEEN**
5 **REMEDIED?**

6 **A.** No. While the proposition that HM 5.3 Revised should rise or fall on its own
7 merits is reasonable, it is also the case that a number of the problems that this
8 Commission found with HM 3.1 and HM 5.0a still remain.

Deleted: HM 5.3

9 **Q. PLEASE DESCRIBE THESE PROBLEMS.**

10 **A.** In particular, HM 5.3 Revised fails to address two major concerns the
11 Commission has raised in earlier decisions: (1) problems with particular inputs,
12 such as placement costs, drop lengths, and switch investments,¹⁴⁶ and (2) the
13 need validate certain model outputs, such as loop lengths.¹⁴⁷ With regard to the
14 former, I note that a large number of outside plant and other inputs are the
15 same as the HM 5.0a values about which the Commission previously
16 expressed concern -- in general, in contrast to the inputs used in VzLoop, HM
17 5.3 Revised's inputs are the result of Mr. Donovan's opinions, and have no
18 basis whatsoever in what a real-world carrier can expect to pay for such inputs
19 in Washington.

Deleted: HM 5.3

Deleted: HM 5.3

¹⁴⁵ New Jersey Order at p. 27.

¹⁴⁶ 1998 Eighth Supp. Order at ¶¶ 93, 134, 285.

¹⁴⁷ Tenth Supplemental Order at ¶ 271.

1 With regard to validation, Dr. Mercer has not presented the types of
2 comparisons to actual data (e.g., loop lengths) that the Commission suggested
3 in earlier orders. This omission is not surprising given that, as demonstrated
4 herein, such comparisons only serve to demonstrate the imprecise nature of

5 HM 5.3 Revised

Deleted: HM 5.3

6 **Q. PLEASE EXPLAIN.**

7 **A.** A revealing test is to compare the average loop lengths for each wire center
8 produced by the model to corresponding external measures of average loop
9 length. For the latter, I used the average loop lengths that Mr. Spinks used in
10 his modified version of HM 5.3 Revised. In particular, I calculated the absolute
11 percentage deviation between the HM 5.3 Revised loop length and Mr. Spinks'
12 loop length for each wire center. For HM 5.3 Revised, these percentages
13 averaged 61 percent, ranging from 0 percent to 635 percent. In contrast, when
14 I performed the same test on VzLoop loop lengths, the average deviation was
15 only 15 percent, ranging from 0 percent to 108 percent.

17 **ARE BASED ON "TRUING UP" HM 5.3 REVISED'S LOOP LENGTHS TO**
18 **THESE EXTERNAL MEASURES, A RELIABLE WAY TO ESTIMATE UNE**
19 **COSTS?**

Deleted: HM 5.3

Deleted: HM 5.3

20 **A.** No. As I described earlier, not only does HM 5.3 Revised produce imprecise
21 loop lengths, it tends to place the wrong types of facilities (e.g., cables of a
22 particular size) in the wrong places. Consequently, a mere "true up" of
23 distances will not guarantee that the cost outputs are reliable.

Deleted: HM 5.3

1 X. MAJOR COST CATEGORIES IN **HM 5.3 REVISED**

2
3 Q. PLEASE IDENTIFY THE MAJOR CATEGORIES OF LOOP INVESTMENT.

4 A. Valid estimates of economic costs require that a cost model's inputs comport
5 with the costs and operating conditions Verizon NW experiences. An
6 informative way to identify the most critical inputs is to determine proportions of
7 total investment (e.g., ordinary loops) accounted for by specific types of
8 facilities. In selecting the inputs that ultimately result in total investment, Mr.
9 Donovan generally has not relied upon data specific to Verizon NW, but rather
10 has used his own unverified judgment to substantiate a substantial number of
11 **HM 5.3 Revised's** inputs and investments (e.g., engineering and placement of
12 cable, support structures, DLC engineering and installation, etc.). In contrast,
13 the corresponding inputs to VzLoop are based on Verizon NW's recent
14 experience providing service in Washington (e.g., vendor contracts and the
15 like). The identification of the critical investment categories below highlights the
16 extent to which **HM 5.3 Revised's** costs depend on Mr. Donovan's
17 unsubstantiated opinions, as opposed to any realistic and accurate measure of
18 the actual costs Verizon NW expects to incur when building and operating its
19 network.

20
21 **TABLE 10**

	HM 5.3 Revised		VzLoop	
	Investment/Line	% of total	Investment/Line	% of total
Poles	\$26.57	5.93%	\$46.75	4.21%
Aerial	\$54.27	12.12%	\$70.65	6.36%
Buried	\$105.66	23.59%	\$187.81	16.91%
Underground	\$13.44	3.00%	\$49.03	4.42%
Conduit	\$44.53	9.94%	\$283.69	25.55%
DLC	\$120.29	26.86%	\$301.18	27.12%

Equipment				
SAI	\$8.74	1.95%	\$17.13	1.54%
Drop				
Terminal	\$43.06	9.61%	\$40.27	3.63%
Drop Wire	\$13.64	3.05%	\$73.14	6.59%
NID	\$17.64	3.94%	\$40.83	3.68%
Total	\$447.84		\$1,110.48

This table shows that, in each model, the costs for cable and structure account for about one-half of the total investment; and DLC equipment accounts for approximately one-quarter of the total investment.¹⁴⁸ Further, HM 5.3 Revised's investments are generally about one half VzLoop's investment levels across the board. While a proper cost study requires accurate measurement of *all* cost inputs, it is essential to develop accurate cost estimates for the more critical inputs. HM 5.3 Revised fails miserably in this regard.

XI. CONCLUSIONS

Q. PLEASE SUMMARIZE YOUR CONCLUSIONS.

A. HM 5.3 Revised should not be used to set UNE rates for Verizon NW in Washington. The Model does not comply with proper forward-looking cost methodologies (including those called for by TELRIC), fails the validation tests to which it is subjected, and is based on an incorrect representation of the economics and operations of local exchange networks. Numerous errors are also built into the HM 5.3 Revised's estimating methodologies and input assumptions, resulting in incredibly understated forward-looking costs of the

¹⁴⁸ Of course, total investment also depends on the quantities of each component. As I discussed earlier, HM 5.3 Revised generally produces insufficient (or imprecise) quantities of loop facilities as well.

1 network required to provide reliable service in Verizon NW's Washington
2 territory.

3 In particular, HM 5.3 Revised assumes that service could be provided in
4 Washington for only 30 percent of Verizon NW's current investment levels, and
5 that Verizon NW's network could be operated with little more than one-half of
6 the out-of-pocket expenses (and one-half the labor force) currently experienced.

Deleted: HM 5.3

Deleted: only

7 Similarly, Mr. Donovan's ill-advised engineering and installation labor estimates
8 have the incredible implication that an entire network serving all of Verizon
9 NW's 1.1 million lines could be completely installed in one year by a labor force
10 of fewer than 900 workers.

Deleted: little over

Deleted: 800

11 For the foregoing reasons, and others discussed in the testimonies of
12 Messrs. Dippon, Richter, and Murphy, the Commission should not rely upon HM
13 5.3 Revised, to any extent, to establish Verizon NW's UNE rates.

Deleted: HM 5.3

14 **Q. DOES THIS CONCLUDE YOUR REPLY TESTIMONY?**

15 **A.** Yes.
