DOCKET NO. UG-22 _____

EXH. AMM-3

ADRIEN M. MCKENZIE

REPRESENTING AVISTA CORPORATION

I. DESCRIPTION OF QUANTITATIVE ANALYSES

1 **Q. What is the purpose of this exhibit?**

2 A. Exh. AMM-3 presents details of my analysis of the cost of equity for the
3 jurisdictional electric and natural gas utility operations of Avista Corp. (“Avista” or “the
4 Company”). First, I will briefly summarize the concept of the cost of equity, along with the
5 risk-return tradeoff principle fundamental to capital markets. Next, I describe my
6 applications of the Discounted Cash Flow (“DCF”) model, the Capital Asset Pricing Model
7 (“CAPM”), the empirical form of the CAPM (“ECAPM”), a risk premium analyses based on
8 allowed equity returns for electric utilities, and reference to expected rates of return for
9 electric utilities. This exhibit also presents a market-based test to my utility quantitative
10 analyses by applying the DCF model to a group of low-risk non-utility firms.

A. Overview

11 **Q. What fundamental economic principle underlies any evaluation of**
12 **investors’ required return on equity (“ROE”)?**

13 A. The fundamental economic principle underlying the cost of equity concept is
14 the notion that investors are risk averse. In capital markets where relatively risk-free assets
15 are available (*e.g.*, U.S. Treasury securities), investors can be induced to hold riskier assets
16 only if they are offered a premium, or additional return, above the rate of return on a
17 risk-free asset. Because all assets compete with each other for investor funds, riskier assets
18 must yield a higher expected rate of return than safer assets to induce investors to hold them.

19 Given this risk-return tradeoff, the required rate of return (k) from an asset (i) can be
20 generally expressed as:

1
$$k_i = R_f + RP_i$$

2 where: R_f = Risk-free rate of return, and
3 RP_i = Risk premium required to hold riskier asset i.

4 Thus, the required rate of return for a particular asset at any point in time is a function of: 1)
5 the yield on risk-free assets, and 2) its relative risk, with investors demanding
6 correspondingly larger risk premiums for assets bearing greater risk.

7 **Q. Is there evidence that the risk-return tradeoff principle actually operates**
8 **in the capital markets?**

9 A. Yes. The risk-return tradeoff can be readily documented in segments of the
10 capital markets where required rates of return can be directly inferred from market data and
11 where generally accepted measures of risk exist. Bond yields, for example, reflect investors'
12 expected rates of return, and bond ratings measure the risk of individual bond issues.
13 Comparing the observed yields on government securities, which are considered free of
14 default risk, to the yields on bonds of various rating categories demonstrates that the risk-
15 return tradeoff does, in fact, exist.

16 **Q. Does the risk-return tradeoff observed with fixed income securities**
17 **extend to common stocks and other assets?**

18 A. It is widely accepted that the risk-return tradeoff evidenced with long-term
19 debt extends to all assets. Documenting the risk-return tradeoff for assets other than fixed
20 income securities, however, is complicated by two factors. First, there is no standard
21 measure of risk applicable to all assets. Second, for most assets – including common stock –
22 required rates of return cannot be directly observed. Yet there is every reason to believe that
23 investors exhibit risk aversion in deciding whether or not to hold common stocks and other
24 assets, just as when choosing among fixed-income securities.

1 **Q. Is this risk-return tradeoff limited to differences between firms?**

2 A. No. The risk-return tradeoff principle applies not only to investments in
3 different firms, but also to different securities issued by the same firm. The securities issued
4 by a utility vary considerably in risk because they have different characteristics and
5 priorities. As noted earlier, long-term debt is senior among all capital in its claim on a
6 utility's net revenues and is, therefore, the least risky. The last investors in line are common
7 shareholders. They receive only the net revenues, if any, remaining after all other claimants
8 have been paid. As a result, the rate of return that investors require from a utility's common
9 stock, the most junior and riskiest of its securities, must be considerably higher than the
10 yield offered by the utility's senior, long-term debt.

11 **Q. What are the challenges in determining a just and reasonable ROE for a**
12 **regulated enterprise?**

13 A. The actual return investors require is unobservable. Different methodologies
14 have been developed to estimate investors' expected and required return on capital, but all
15 such methodologies are merely theoretical tools and generally produce a range of estimates,
16 based on different assumptions and inputs. The DCF method, which is frequently
17 referenced and relied on by regulators, is only one theoretical approach to gain insight into
18 the return investors require; there are numerous other methodologies for estimating the cost
19 of capital and the ranges produced by the different approaches can vary widely. As a result,
20 financial analysts and regulators routinely consider the results of alternative approaches in
21 determining allowed ROEs.

22 **Q. What does this imply with respect to estimating the ROE for a utility?**

23 A. Although the ROE cannot be observed directly, it is a function of the returns
24 available from other investment alternatives and the risks to which the equity capital is

1 exposed. Because it is not readily observable, the ROE for a particular utility must be
2 estimated by analyzing information about capital market conditions generally, assessing the
3 relative risks of the company specifically, and employing various quantitative methods that
4 focus on investors' required rates of return. These various quantitative methods typically
5 attempt to infer investors' required rates of return from stock prices, interest rates, or other
6 capital market data. Consistent with FERC's conclusion that "[t]here is significant evidence
7 indicating that combining estimates from different models is more accurate than relying on a
8 single model,"¹ my evaluation of a fair ROE for the Company considers the results of
9 multiple financial models, including the DCF, CAPM (and the related ECAPM), risk
10 premium, and expected earnings approaches.

B. Comparable Risk Proxy Group

11 **Q. How do you implement quantitative methods to estimate the cost of**
12 **common equity for Avista?**

13 A. Application of quantitative methods to estimate the cost of common equity
14 requires observable capital market data, such as stock prices and beta values. Moreover,
15 even for a firm with publicly traded stock, the cost of common equity can only be estimated.
16 As a result, applying quantitative models using observable market data only produces an
17 estimate that inherently includes some degree of observation error. Thus, the accepted
18 approach to increase confidence in the results is to apply alternative quantitative methods to
19 a proxy group of publicly traded companies that investors regard as risk-comparable. The
20 results of the analysis for the sample of companies are relied upon to establish a range of
21 reasonableness for the cost of equity for the specific company at issue.

¹ *Coakley v. Bangor Hydro-Elec. Co.*, 165 FERC ¶ 61,030 at P 38 (2018); *Assan of Bus. Advocating Tariff Equity v. Midcontinent Indep. Sys. Operator, Inc.*, 165 FERC ¶ 61,118 at P 40 (2018).

1 **Q. What specific proxy group of utilities do you rely on for your analyses?**

2 A. My analyses relied on a proxy group composed of 16 companies, which I
3 refer to as the “Utility Group.” In order to develop this group, I began with the following
4 criteria:

- 5 1. Included in the Electric Utility Industry groups compiled by The Value Line
6 Investment Survey (“Value Line”).
- 7 2. Corporate credit ratings from Standard & Poor’s Global Ratings (“S&P”) and
8 Moody’s Investors Service (“Moody’s”) corresponding to one notch above
9 and below the Company’s current ratings. For S&P, this results in a ratings
10 range of BBB-, BBB, and BBB+; for Moody’s the range is Baa3, Baa2, or
11 Baa1.
- 12 3. No ongoing involvement in a major merger or acquisition that would distort
13 quantitative results.
- 14 4. No cuts in dividend payments during the past six months and no
15 announcement of a dividend cut since that time.

16 **Q. Is there any other publicly traded utility that is relevant in establishing a**
17 **proxy group?**

18 A. Yes. Emera Inc. (“Emera”) is primarily engaged in electricity generation,
19 transmission, and distribution; gas transmission and distribution; and utility energy services,
20 and its operations are comparable to those of other electric utilities. While Emera is
21 currently included in Value Line’s “Power Industry” sector, Emera’s operations are
22 dominated by its regulated electric and gas utility operations, which account for
23 approximately 95% of total revenues. U.S. operations constitute 68% of Emera Inc.’s total
24 earnings, and its Florida electric utility operations account for 58% of total rate base
25 investment.² Thus, investors would regard Emera Inc. as a comparable investment

² Emera Inc., *Investors Presentation* (May/June 2021)
https://s25.q4cdn.com/978989322/files/doc_presentations/2021/Emera_June-2021_MarketingPresentation_FINAL.pdf; 2020 SEC Form 40-F for Emera Inc.,
<https://sec.report/Document/0001193125-21-102229/>.

1 alternative that is relevant to an evaluation of the required rate of return for Avista.³

2 **Q. How do you evaluate the risks of the Utility Group relative to Avista?**

3 A. My evaluation of relative risk considers four objective, published
4 benchmarks that are widely relied on in the investment community. Credit ratings are
5 assigned by independent rating agencies for the purpose of providing investors with a broad
6 assessment of the creditworthiness of a firm. Ratings generally extend from triple-A (the
7 highest) to D (in default). Other symbols (*e.g.*, “BBB+”) are used to show relative standing
8 within a category. Because the rating agencies’ evaluation includes virtually all of the
9 factors normally considered important in assessing a firm’s relative credit standing,
10 corporate credit ratings provide a broad, objective measure of overall investment risk that is
11 readily available to investors. Although the credit rating agencies are not immune to
12 criticism, their rankings and analyses are widely cited in the investment community and
13 referenced by investors. Investment restrictions tied to credit ratings continue to influence
14 capital flows, and credit ratings are also frequently used as a primary risk indicator in
15 establishing proxy groups to estimate the cost of common equity.

16 While credit ratings provide the most widely referenced benchmark for investment
17 risks, other quality rankings published by investment advisory services also provide relative
18 assessments of risks that are considered by investors in forming their expectations for
19 common stocks. Value Line’s primary risk indicator is its Safety Rank, which ranges from
20 “1” (Safest) to “5” (Riskiest). This overall risk measure is intended to capture the total risk
21 of a stock, and incorporates elements of stock price stability and financial strength. Given
22 that Value Line is perhaps the most widely available source of investment advisory

³ In addition to Emera, I also considered Algonquin Power & Utilities Company (“Algonquin”), which would be regarded as a comparable utility investment opportunity by investors. Algonquin was excluded due to its ongoing involvement in a major acquisition transaction.

1 information, its Safety Rank provides useful guidance regarding the risk perceptions of
2 investors.

3 The Financial Strength Rating is designed as a guide to overall financial strength and
4 creditworthiness, with the key inputs including financial leverage, business volatility
5 measures, and company size. Value Line's Financial Strength Ratings range from "A++"
6 (strongest) down to "C" (weakest) in nine steps. Finally, Value Line's beta measures a
7 utility's stock price volatility relative to the market as a whole. A stock that tends to respond
8 less to market movements has a beta less than 1.00, while stocks that tend to move more
9 than the market have betas greater than 1.00. Beta is the only relevant measure of
10 investment risk under modern capital market theory, and is widely cited in academics and in
11 the investment industry as a guide to investors' risk perceptions. Moreover, in my
12 experience Value Line is the most widely referenced source for beta in regulatory
13 proceedings. As noted in *New Regulatory Finance*:

14 Value Line is the largest and most widely circulated independent investment
15 advisory service, and influences the expectations of a large number of
16 institutional and individual investors. ... Value Line betas are computed on a
17 theoretically sound basis using a broadly based market index, and they are
18 adjusted for the regression tendency of betas to converge to 1.00.⁴

19 **Q. How do the overall risks of your proxy group compare with Avista?**

20 A. Table 1 compares the Utility Group with Avista across five key indicators of
21 investment risk:

⁴ Roger A. Morin, *New Regulatory Finance*, Pub. Util. Reports (2006) at 71.

1
2
TABLE 1
COMPARISON OF RISK INDICATORS

	<u>Value Line</u>				
	<u>S&P</u>	<u>Moody's</u>	<u>Safety Rank</u>	<u>Financial Strength</u>	<u>Beta</u>
Utility Group	BBB+	Baa2	2	A	0.91
Avista Corp.	BBB	Baa2	2	B++	0.95

3
4
Q. What does this comparison indicate regarding investors' assessment of the relative risk associated with your Utility Group?

5
6
7
8
9
10
11
12
13
A. As shown above, the S&P and Moody's credit ratings for Avista are nearly identical to the average of credit ratings for the Utility Group. Likewise, the average Value Line Safety Rank and Financial Strength measures for the Utility Group are also generally equivalent to those that are assigned to the Company. The average of Value Line's betas for the Utility Group is below, but comparable to Avista's beta. Considered together, this comparison of objective measures, which consider a broad spectrum of risks, including financial and business position, and exposure to firm-specific factors, indicates that investors would likely conclude that the overall investment risks for Avista are comparable to those of the firms in the Utility Group.

14
15
C. Discounted Cash Flow Analyses

16
17
Q. How is the DCF model used to estimate the cost of equity?

18
19
20
A. DCF models attempt to replicate the market valuation process that sets the price investors are willing to pay for a share of a company's stock. The model rests on the assumption that investors evaluate the risks and expected rates of return from all securities in the capital markets. Given these expectations, the price of each stock is adjusted by the market until investors are adequately compensated for the risks they bear. Therefore, we can look to the market to determine what investors believe a share of common stock is worth.

1 By estimating the cash flows investors expect to receive from the stock in the way of future
2 dividends and capital gains, we can calculate their required rate of return. That is, the cost
3 of equity is the discount rate that equates the current price of a share of stock with the
4 present value of all expected cash flows from the stock. The formula for the general form of
5 the DCF model is as follows:

$$P_0 = \frac{D_1}{(1+k_e)^1} + \frac{D_2}{(1+k_e)^2} + \dots + \frac{D_t}{(1+k_e)^t} + \frac{P_t}{(1+k_e)^t}$$

6

7 where: P_0 = Current price per share;
8 P_t = Expected future price per share in period t;
9 D_t = Expected dividend per share in period t;
10 k_e = Cost of common equity.

11 **Q. What form of the DCF model is customarily used to estimate the cost of**
12 **equity in rate cases?**

13 A. Rather than developing annual estimates of cash flows into perpetuity, the
14 DCF model can be simplified to a “constant growth” form:⁵

$$P_0 = \frac{D_1}{k_e - g}$$

15

16 where: P_0 = Current price per share;
17 D_1 = Expected dividend per share in the coming year;
18 k_e = Cost of equity;
19 g = Investors’ long-term growth expectations.

20 The cost of equity (k_e) can be isolated by rearranging terms:

$$k_e = \frac{D_1}{P_0} + g$$

21

⁵ The constant growth DCF model is dependent on a number of assumptions, which in practice are never strictly met. These include a constant growth rate for both dividends and earnings; a stable dividend payout ratio; the discount rate exceeds the growth rate; a constant growth rate for book value and price; a constant earned rate of return on book value; no sales of stock at a price above or below book value; a constant price-earnings ratio; a constant discount rate (*i.e.*, no changes in risk or interest rate levels and a flat yield curve); and all of the above extend to infinity.

1 This constant growth form of the DCF model recognizes that the rate of return to
2 stockholders consists of two parts: 1) dividend yield (D_1/P_0), and 2) growth (g). In other
3 words, investors expect to receive a portion of their total return in the form of current
4 dividends and the remainder through price appreciation.

5 **Q. What steps are required to apply the DCF model?**

6 A. The first step in implementing the constant growth DCF model is to
7 determine the expected dividend yield (D_1/P_0) for the firm in question. This is usually
8 calculated based on an estimate of dividends to be paid in the coming year divided by the
9 current price of the stock. The second step is to estimate investors' long-term growth
10 expectations (g) for the firm. The final step is to sum the firm's dividend yield and estimated
11 growth rate to arrive at an estimate of its cost of common equity.

12 **Q. How is the dividend yield for the Utility Group determined?**

13 A. Estimates of dividends to be paid by each of these utilities over the next
14 twelve months, obtained from Value Line, serve as D_1 . This annual dividend is then divided
15 by a 30-day average stock price for each utility to arrive at the expected dividend yield. The
16 stock prices, expected dividends, and resulting dividend yields for the firms in the Utility
17 Group are presented on page 1 of Exh. AMM-7.

18 **Q. What is the next step in applying the constant growth DCF model?**

19 A. The next step is to evaluate long-term growth expectations, or “ g ”, for the
20 firm in question. In constant growth DCF theory, earnings, dividends, book value, and
21 market price are all assumed to grow in lockstep, and the growth horizon of the DCF model
22 is infinite. But implementation of the DCF model is more than just a theoretical exercise; it
23 is an attempt to replicate the mechanism investors used to arrive at observable stock prices.

1 A wide variety of techniques can be used to derive growth rates, but the only “g” that
2 matters in applying the DCF model is the value that investors expect.

3 **Q. What are investors most likely to consider in developing their long-term**
4 **growth expectations?**

5 A. Implementation of the DCF model is solely concerned with replicating the
6 forward-looking evaluation of real-world investors. In the case of utilities, dividend growth
7 rates are not likely to provide a meaningful guide to investors’ current growth expectations.
8 This is because utilities have significantly altered their dividend policies in response to more
9 accentuated business risks in the industry, with the payout ratios falling significantly from
10 historical levels. As a result, dividend growth in the utility industry has lagged growth in
11 earnings as utilities conserve financial resources to provide a hedge against heightened
12 uncertainties.

13 A measure that plays a pivotal role in determining investors’ long-term growth
14 expectations are future trends in earnings per share (“EPS”), which provide the source for
15 future dividends and ultimately support share prices. The importance of earnings in
16 evaluating investors’ expectations and requirements is well accepted in the investment
17 community, and surveys of analytical techniques relied on by professional analysts indicate
18 that growth in earnings is far more influential than trends in dividends per share (“DPS”).

19 The availability of projected EPS growth rates also is key to investors relying on this
20 measure as compared to future trends in DPS. Apart from Value Line, investment advisory
21 services do not generally publish comprehensive DPS growth projections, and this scarcity
22 of dividend growth rates relative to the abundance of earnings forecasts attests to their
23 relative influence. The fact that securities analysts focus on EPS growth, and that DPS

1 growth rates are not routinely published, indicates that projected EPS growth rates are likely
2 to provide a superior indicator of the future long-term growth expected by investors.

3 **Q. Do the growth rate projections of security analysts consider historical**
4 **trends?**

5 A. Yes. Professional security analysts study historical trends extensively in
6 developing their projections of future earnings. Hence, to the extent there is any useful
7 information in historical patterns, that information is incorporated into analysts' growth
8 forecasts.

9 **Q. Did Professor Myron J. Gordon, who pioneered the DCF approach,**
10 **recognize the pivotal role that earnings play in forming investors' expectations?**

11 A. Yes. Dr. Gordon specifically recognized that "it is the growth that investors
12 expect that should be used" in applying the DCF model and he concluded:

13 A number of considerations suggest that investors may, in fact, use earnings
14 growth as a measure of expected future growth."⁶

15 **Q. Are analysts' assessments of growth rates appropriate for estimating**
16 **investors' required return using the DCF model?**

17 A. Yes. In applying the DCF model to estimate the cost of common equity, the
18 only relevant growth rate is the forward-looking expectations of investors that are captured
19 in current stock prices. Investors, just like securities analysts and others in the investment
20 community, do not know how the future will actually turn out. They can only make
21 investment decisions based on their best estimate of what the future holds in the way of
22 long-term growth for a particular stock, and securities prices are constantly adjusting to
23 reflect their assessment of available information.

⁶ Myron J. Gordon, *The Cost of Capital to a Public Utility*, MSU Public Utilities Studies (1974) at 89.

1 Any claims that analysts' estimates are not relied upon by investors are illogical
2 given the reality of a competitive market for investment advice. If financial analysts'
3 forecasts do not add value to investors' decision making, then it is irrational for investors to
4 pay for these estimates. Similarly, those financial analysts who fail to provide reliable
5 forecasts will lose out in competitive markets relative to those analysts whose forecasts
6 investors find more credible. The reality that analyst estimates are routinely referenced in
7 the financial media and in investment advisory publications (*e.g.*, Value Line) implies that
8 investors use them as a basis for their expectations.

9 While the projections of securities analysts may be proven optimistic or pessimistic
10 in hindsight, this is irrelevant in assessing the expected growth that investors have
11 incorporated into current stock prices, and any bias in analysts' forecasts—whether
12 pessimistic or optimistic—is irrelevant if investors share analysts' views. Earnings growth
13 projections of security analysts provide the most frequently referenced guide to investors'
14 views and are widely accepted in applying the DCF model. As explained in *New Regulatory*
15 *Finance*:

16 Because of the dominance of institutional investors and their influence on
17 individual investors, analysts' forecasts of long-run growth rates provide a
18 sound basis for estimating required returns. Financial analysts exert a strong
19 influence on the expectations of many investors who do not possess the
20 resources to make their own forecasts, that is, they are a cause of *g* [growth].
21 The accuracy of these forecasts in the sense of whether they turn out to be
22 correct is not an issue here, as long as they reflect widely held expectations.⁷

23 **Q. Have regulators also recognized that analysts' growth rate estimates are**
24 **an important and meaningful guide to investors' expectations?**

25 A. Yes. The Kentucky Public Service Commission has indicated its preference
26 for relying on analysts' projections in establishing investors' expectations:

⁷ Roger A. Morin, *New Regulatory Finance*, Pub. Util. Reports, Inc. (2006) at 298 (emphasis added).

1 KU's argument concerning the appropriateness of using investors'
2 expectations in performing a DCF analysis is more persuasive than the AG's
3 argument that analysts' projections should be rejected in favor of historical
4 results. The Commission agrees that analysts' projections of growth will be
5 relatively more compelling in forming investors' forward-looking
6 expectations than relying on historical performance, especially given the
7 current state of the economy.⁸

8 Similarly, FERC has expressed a clear preference for projected EPS growth rates in applying
9 the DCF model to estimate the cost of equity for both electric and natural gas pipeline
10 utilities:

11 Opinion No. 414-A held that the IBES five-year growth forecasts for each
12 company in the proxy group are the best available evidence of the short-term
13 growth rates expected by the investment community. It cited evidence that (1)
14 those forecasts are provided to IBES by professional security analysts, (2)
15 IBES reports the forecast for each firm as a service to investors, and (3) the
16 IBES reports are well known in the investment community and used by
17 investors. The Commission has also rejected the suggestion that the IBES
18 analysts are biased and stated that "in fact the analysts have a significant
19 incentive to make their analyses as accurate as possible to meet the needs of
20 their clients since those investors will not utilize brokerage firms whose
21 analysts repeatedly overstate the growth potential of companies."⁹

22 The Public Utility Regulatory Authority of Connecticut has also noted that "there is
23 not growth in DPS without growth in EPS," and concluded that securities analysts' growth
24 projections have a greater influence over investors' expectations and stock prices.¹⁰ In
25 addition, the Regulatory Commission of Alaska ("RCA") has previously determined that
26 analysts' EPS growth rates provide a superior basis on which to estimate investors'
27 expectations:

28 We also find persuasive the testimony . . . that projected EPS returns are more
29 indicative of investor expectations of dividend growth than historical growth

⁸ *Kentucky Utilities Co.*, Case No. 2009-00548 (Ky PSC Jul. 30, 2010) at 30-31.

⁹ *Kern River Gas Transmission Co.*, 126 FERC ¶ 61,034 at P 121 (2009) (footnote omitted).

¹⁰ *Decision*, Docket No. 13-02-20 (Sept. 24, 2013).

1 data because persons making the forecasts already consider the historical
2 numbers in their analyses.¹¹

3 The RCA has concluded that arguments against exclusive reliance on analysts' EPS growth
4 rates to apply the DCF model "are not convincing."¹²

5 **Q. What are security analysts currently projecting in the way of growth for**
6 **the firms in the Utility Proxy Group?**

7 A. The projected EPS growth rates for each of the firms in the Utility Group
8 reported by Value Line, IBES,¹³ and Zacks Investment Research ("Zacks") are displayed on
9 page 2 of Exh. AMM-7.

10 **Q. How else are investors' expectations of future long-term growth**
11 **prospects often estimated for use in the constant growth DCF model?**

12 A. In constant growth theory, growth in book equity will be equal to the product
13 of the earnings retention ratio (one minus the dividend payout ratio) and the earned rate of
14 return on book equity. Furthermore, if the earned rate of return and the payout ratio are
15 constant over time, growth in earnings and dividends will be equal to growth in book value.
16 Despite the fact that these conditions are seldom, if ever, met in practice, this "sustainable
17 growth" approach may provide a rough guide for evaluating a firm's growth prospects and is
18 frequently proposed in regulatory proceedings.

19 The sustainable growth rate is calculated by the formula, $g = br + sv$, where "b" is the
20 expected retention ratio, "r" is the expected earned return on equity, "s" is the percent of
21 common equity expected to be issued annually as new common stock, and "v" is the equity
22 accretion rate. Under DCF theory, the "sv" factor is a component of the growth rate
23 designed to capture the impact of issuing new common stock at a price above, or below,

¹¹ Regulatory Commission of Alaska, U-07-76(8) at 65, n. 258.

¹² Regulatory Commission of Alaska, U-08-157(10) at 36.

¹³ Formerly I/B/E/S International, Inc., IBES growth rates are now compiled and published by Refinitiv.

1 book value. The sustainable, “br+sv” growth rates for each firm in the Utility Group are
2 summarized on page 2 of Exh. AMM-7, with the underlying details being presented on Exh.
3 AMM-8.

4 The sustainable growth rate analysis shown in Exhibit AMM-8 incorporates an
5 “adjustment factor” because Value Line’s reported returns are based on year-end book
6 values. Since earnings is a flow over the year while book value is determined at a given
7 point in time, the measurement of earnings and book value are distinct concepts. It is this
8 fundamental difference between a flow (earnings) and point estimate (book value) that
9 makes it necessary to adjust to mid-year in calculating the ROE. Given that book value will
10 increase or decrease over the year, using year-end book value (as Value Line does)
11 understates or overstates the average investment that corresponds to the flow of earnings.
12 To address this concern, earnings must be matched with a corresponding representative
13 measure of book value, or the resulting ROE will be distorted. The adjustment factor
14 determined in Exhibit AMM-8 is solely a means of converting Value Line’s end-of-period
15 values to an average return over the year.

16 **Q. What cost of equity estimates are implied for the Utility Group using the**
17 **DCF model?**

18 A. After combining the dividend yields and respective growth projections for
19 each utility, the resulting cost of equity estimates are shown on page 3 of Exh. AMM-7.

20 **Q. In evaluating the results of the constant growth DCF model, is it**
21 **appropriate to eliminate illogical low or high-end values?**

22 A. Yes. In applying quantitative methods to estimate the cost of equity, it is
23 essential that the resulting values pass fundamental tests of reasonableness and economic

1 logic. Accordingly, DCF estimates that are implausibly low or high should be eliminated
2 when evaluating the results of this method.

3 **Q. How do you evaluate DCF estimates at the low end of the range?**

4 A. I base my evaluation of DCF estimates at the low end of the range on the
5 fundamental risk-return tradeoff, which holds that investors will only take on more risk if
6 they expect to earn a return to compensate them for the greater uncertainty. Because
7 common stocks lack the protections associated with an investment in long-term bonds, a
8 utility's common stock imposes far greater risks on investors. As a result, the rate of return
9 that investors require from a utility's common stock is considerably higher than the yield
10 offered by senior, long-term debt. Consistent with this principle, DCF results that are not
11 sufficiently higher than the yields available on less risky utility bonds must be eliminated.

12 **Q. Have similar tests been applied by regulators?**

13 A. Yes. FERC has noted that adjustments are justified where applications of the
14 DCF approach produce illogical results. FERC previously evaluated DCF results against
15 observable yields on long-term public utility debt and recognized that it is appropriate to
16 eliminate estimates that do not sufficiently exceed this threshold,¹⁴ and also exclude
17 estimates that are "irrationally or anomalously high."¹⁵

18 **Q. What do you conclude regarding the reasonableness of DCF values at the**
19 **low end of the range of results?**

20 A. As highlighted on page 3 of Exhibit AMM-7, I eliminate a low-end DCF
21 estimate of 4.4 percent. Based on my professional experience and the risk-return tradeoff

¹⁴ See, e.g., *Southern California Edison Co.*, 131 FERC ¶ 61,020 at P 55 (2010).

¹⁵ *Ass'n of Bus. Advocating Tariff Equity v. Midcontinent Indep. Sys. Operator, Inc.*, 171 FERC ¶ 61,154 at P 152 (2020).

1 principle that is fundamental to finance, it is inconceivable that investors are not requiring a
2 substantially higher rate of return for holding common stock.

3 **Q. Do you also recommend excluding estimates at the high end of the range**
4 **of DCF results?**

5 A. Yes. Based on my review of the array of DCF results, I also exclude a single
6 high-end cost of equity estimate of 15.5 percent. After excluding this value, the upper end
7 of the cost of common equity range produced by the DCF analysis is set by a cost of equity
8 estimate of 13.6 percent. While a 13.6 percent cost of equity estimate may exceed the
9 majority of the remaining values, low-end DCF estimates in the 6.2 to 6.3 percent range are
10 assuredly far below investors' required rate of return. Taken together and considered along
11 with the balance of the results, the remaining values provide a reasonable basis on which to
12 frame the range of plausible DCF estimates and evaluate investors' required rate of return.

13 **Q. What cost of equity is implied by your DCF results for the Utility Group?**

14 A. As shown on page 3 of Exh. AMM-7 and summarized in Table 2, below, after
15 eliminating illogical values, application of the constant growth DCF model results in the
16 following cost of equity estimates:

17 **TABLE 2**
18 **DCF RESULTS – UTILITY GROUP**

<u>Growth Rate</u>	<u>Average</u>
Value Line	9.0%
IBES	9.0%
Zacks	8.7%
br + sv	8.9%

D. Capital Asset Pricing Model

1 **Q. Please describe the CAPM.**

2 A. The CAPM is a theory of market equilibrium that measures risk using the
3 beta coefficient. Assuming investors are fully diversified, the relevant risk of an individual
4 asset (*e.g.*, common stock) is its volatility relative to the market as a whole, with beta
5 reflecting the tendency of a stock's price to follow changes in the market. A stock that tends
6 to respond less to market movements has a beta less than 1.00, while stocks that tend to
7 move more than the market have betas greater than 1.00. The CAPM is mathematically
8 expressed as:

9
$$R_j = R_f + \beta_j(R_m - R_f)$$

10 where: R_j = required rate of return for stock j ;
11 R_f = risk-free rate;
12 R_m = expected return on the market portfolio; and,
13 β_j = beta, or systematic risk, for stock j .

14 Under the CAPM formula above, a stock's required return is a function of the risk-
15 free rate (R_f), plus a risk premium that is scaled to reflect the relative volatility of a firm's
16 stock price, as measured by beta (β). Like the DCF model, the CAPM is an *ex-ante*, or
17 forward-looking model based on expectations of the future. As a result, in order to produce
18 a meaningful estimate of investors' required rate of return, the CAPM must be applied using
19 estimates that reflect the expectations of actual investors in the market, not with backward-
20 looking, historical data.

21 **Q. How do you apply the CAPM to estimate the cost of common equity?**

22 A. Application of the CAPM to the Utility Group based on a forward-looking
23 estimate for investors' required rate of return from common stocks is presented on Exh.
24 AMM-9. In order to capture the expectations of today's investors in current capital markets,

1 the expected market rate of return is estimated by conducting a DCF analysis on the
2 dividend paying firms in the S&P 500.

3 The dividend yield for each firm is obtained from Value Line, and the growth rate is
4 equal to the average of the earnings growth projections for each firm published by Value
5 Line, IBES, and Zacks with each firm's dividend yield and growth rate being weighted by its
6 proportionate share of total market value. Based on the weighted average of the projections
7 for the individual firms, current estimates imply an average growth rate over the next five
8 years of 11.4 percent. Combining this average growth rate with a year-ahead dividend yield
9 of 1.9 percent results in a current cost of common equity estimate for the market as a whole
10 (R_m) of 13.3 percent.¹⁶ Subtracting a 2.0 percent risk-free rate based on the average yield on
11 30-year Treasury bonds for the six months ending November 2021 produces a market equity
12 risk premium of 11.3 percent.

13 **Q. What is the source of the beta values you used to apply the CAPM?**

14 A. As noted earlier in the development of my proxy group, I rely on the beta
15 values reported by Value Line, which in my experience is the most widely referenced source
16 for beta in regulatory proceedings.

17 **Q. What else should be considered in applying the CAPM?**

18 A. Financial research indicates that the CAPM does not fully account for
19 observed differences in rates of return attributable to firm size. Accordingly, a modification
20 is required to account for this size effect. As explained by Morningstar:

21 One of the most remarkable discoveries of modern finance is the finding of a
22 relationship between firm size and return. On average, small companies have
23 higher returns than larger ones. . . . The relationship between firm size and

¹⁶ Any difference in the summation due to rounding.

1 return cuts across the entire size spectrum; it is not restricted to the smallest
2 stocks.¹⁷

3 According to the CAPM, the expected return on a security should consist of the
4 riskless rate, plus a premium to compensate for the systematic risk of the particular security.
5 The degree of systematic risk is represented by the beta coefficient. The need for the size
6 adjustment arises because differences in investors' required rates of return that are related to
7 firm size are not fully captured by beta. To account for this, researchers have developed size
8 premiums that need to be added to CAPM cost of equity estimates to account for the level of
9 a firm's market capitalization in determining the CAPM cost of equity.¹⁸ Accordingly, my
10 CAPM analyses incorporated an adjustment to recognize the impact of size distinctions, as
11 measured by the market capitalization for the firms in the Utility Group.

12 **Q. Is this size adjustment related to the relative size of Avista as compared**
13 **with the proxy group?**

14 A. No. I am not proposing to apply a general size risk premium in evaluating a
15 fair and reasonable ROE for the Company and my recommendation does not include any
16 adjustment related to the relative size of Avista. Rather, this size adjustment is specific to
17 the CAPM and merely corrects for an observed inability of the beta measure to fully reflect
18 the risks perceived by investors for the firms in the proxy groups. As FERC has recognized,
19 "This type of size adjustment is a generally accepted approach to CAPM analyses."¹⁹

¹⁷ Morningstar, *2015 Ibbotson SBBI Classic Yearbook*, at p. 99 (footnote omitted).

¹⁸ Originally compiled by Ibbotson Associates and published in their annual yearbook entitled, "Stocks, Bonds, Bills and Inflation," these size premia are now developed by Duff & Phelps and presented in its *Valuation Handbook – Guide to Cost of Capital*.

¹⁹ Opinion No. 531-B, 150 FERC ¶ 61,165 at P 117 (2015).

1 **Q. What cost of equity is indicated for the Utility Group using the CAPM**
2 **approach?**

3 A. As shown on page 1 of Exh. AMM-9, the CAPM approach implies an
4 average ROE of 12.1 percent, and 12.6 percent after adjusting for the impact of firm size.

5 **Q. Do you also apply the CAPM using forecasted bond yields?**

6 A. Yes. As discussed in Exh. AMM-1T, widely recognized economic
7 forecasting services indicate that interest rates are expected to increase over the period when
8 the rates established in this proceeding will be in effect. Accordingly, in addition to the use
9 of current bond yields, I also apply the CAPM based on the forecasted long-term Treasury
10 bond yields developed based on projections for 2023 and 2024 published by Blue Chip
11 Financial Forecast. As shown on page 2 of Exh. AMM-9, incorporating a forecasted
12 Treasury bond yield implies an average cost of equity estimate of 12.4 percent for the Utility
13 Group, and 12.8 percent after adjusting for the impact of relative size.

E. Empirical Capital Asset Pricing Model

14 **Q. How does the ECAPM approach differ from traditional applications of**
15 **the CAPM?**

16 A. Empirical tests of the CAPM have shown that low-beta securities earn returns
17 somewhat higher than the CAPM would predict, and high-beta securities earn less than
18 predicted. In other words, the CAPM tends to overstate the actual sensitivity of the cost
19 of capital to beta, with low-beta stocks tending to have higher returns and high-beta
20 stocks tending to have lower risk returns than predicted by the CAPM. This is illustrated
21 graphically in the figure below:

1
2 **FIGURE 1**
CAPM – PREDICTED VS. OBSERVED RETURNS

3 Because the betas of utility stocks, including those in the Utility Group, are generally less
4 than 1.0, this implies that cost of equity estimates based on the traditional CAPM would
5 understate the cost of equity. This empirical finding is widely reported in the finance
6 literature, as summarized in *New Regulatory Finance*:

7 As discussed in the previous section, several finance scholars have developed
8 refined and expanded versions of the standard CAPM by relaxing the
9 constraints imposed on the CAPM, such as dividend yield, size, and
10 skewness effects. These enhanced CAPMs typically produce a risk-return
11 relationship that is flatter than the CAPM prediction in keeping with the
12 actual observed risk-return relationship. The ECAPM makes use of these
13 empirical findings.²⁰

14 As discussed in *New Regulatory Finance*, based on a review of the empirical
15 evidence, the expected return on a security is related to its risk by the ECAPM, which is
16 represented by the following formula:

²⁰ Roger A. Morin, *New Regulatory Finance*, Pub. Util. Reports, Inc. (2006) at 189.

1
$$R_j = R_f + 0.25(R_m - R_f) + 0.75[\beta_j(R_m - R_f)]$$

2 where: R_j = required rate of return for stock j;
3 R_f = risk-free rate;
4 R_m = expected return on the market portfolio; and,
5 β_j = beta, or systematic risk, for stock j.

6 Like the CAPM formula presented earlier, the ECAPM represents a stock's required return
7 as a function of the risk-free rate (R_f), plus a risk premium. In the formula above, this risk
8 premium is composed of two parts: (1) the market risk premium ($R_m - R_f$) weighted by a
9 factor of 25 percent, and (2) a company-specific risk premium based on the stocks relative
10 volatility [$(\beta)(R_m - R_f)$] weighted by 75 percent. This ECAPM equation, and its associated
11 weighting factors, recognizes the observed relationship between standard CAPM estimates
12 and the cost of capital documented in the financial research, and corrects for the understated
13 returns that would otherwise be produced for low beta stocks.

14 **Q. Is the use of the ECAPM consistent with the use of Value Line betas?**

15 A. Yes. Value Line beta values are adjusted for the observed tendency of beta to
16 converge toward the mean value of 1.00 over time. The purpose of this adjustment is to
17 refine beta values determined using historical data to better match forward-looking estimates
18 of beta, which are the relevant parameter in applying the CAPM or ECAPM models.
19 Meanwhile, the ECAPM does not involve any adjustment to beta whatsoever. Rather, it
20 represents a formal recognition of findings in the financial literature that the observed risk-
21 return tradeoff illustrated in Figure 1 is flatter than predicted by the CAPM. In other words,
22 even if a firm's beta value were estimated with perfect precision, the CAPM would still
23 understate the return for low-beta stocks and overstate the return for high-beta stocks. The

1 ECAPM and the use of adjusted betas represent two separate and distinct issues in
2 estimating returns.

3 **Q. Have other regulators relied on the ECAPM?**

4 A. Yes. For example, a witness for the Staff of the Maryland Public Service
5 Commission noted that “the ECAPM model adjusts for the tendency of the CAPM model to
6 underestimate returns for low Beta stocks,” and concluded that, “I believe under current
7 economic conditions that the ECAPM gives a more realistic measure of the ROE than the
8 CAPM model does.”²¹ The staff of the Colorado Public Utilities Commission has
9 recognized that, “The ECAPM is an empirical method that attempts to enhance the CAPM
10 analysis by flattening the risk-return relationship,”²² and relied on the exact same standard
11 ECAPM equation presented above.²³ The New York Department of Public Service also
12 routinely incorporates the results of the ECAPM approach, which it refers to as the “zero-
13 beta CAPM.”²⁴ The Regulatory Commission of Alaska has also relied on the ECAPM
14 approach, noting that:

15 Tesoro averaged the results it obtained from CAPM and ECAPM while at the
16 same time providing empirical testimony that the ECAPM results are more
17 accurate than [sic] traditional CAPM results. The reasonable investor would
18 be aware of these empirical results. Therefore, we adjust Tesoro’s
19 recommendation to reflect only the ECAPM result.²⁵

20 Similarly, the Montana Public Service Commission more recently concluded that:

²¹ *Direct Testimony and Exhibits of Julie McKenna*, Maryland PSC Case No. 9299 (Oct. 12, 2012) at 9.

²² Proceeding No. 13AL-0067G, *Answer Testimony and Schedules of Scott England* (July 31, 2013) at 47.

²³ *Id.* at 48.

²⁴ *See, e.g.*, New York Department of Public Service, Cases 19-E-0065 19-G-0066, *Prepared Fully Redacted Testimony of Staff Finance Panel* (May 2019) at 94-95.

²⁵ Regulatory Commission of Alaska, Order No. P-97-004(151) (Nov. 27, 2002) at 145.

1 [T]he evidence in this proceeding has convinced the Commission that the
2 Empirical Capital Asset Pricing Model (“ECAPM”) should be the primary
3 method for estimating the [utility’s] cost of equity.”²⁶

4 The Wyoming Office of Consumer Advocate, an independent division of the
5 Wyoming Public Service Commission, has also relied on this ECAPM formula in estimating
6 the cost of equity for a natural gas utility,²⁷ as has the witness for the Office of Arkansas
7 Attorney General.²⁸

8 **Q. What cost of equity estimates are indicated by the ECAPM?**

9 A. My applications of the ECAPM are based on the same forward-looking
10 market rate of return, risk-free rates, and beta values discussed earlier in connections with
11 the CAPM. As shown on page 1 of Exh. AMM-10, applying the forward-looking ECAPM
12 approach to the firms in the Utility Group results in an average ROE estimate of 12.6
13 percent, or 12.9 percent after incorporating the size adjustment corresponding to the market
14 capitalization of the individual utilities.

15 As shown on page 2 of Exh. AMM-10, incorporating a forecasted Treasury bond
16 yield for 2023-2024 implies an average cost of equity for the Utility Group of 12.7 percent,
17 and 13.1 percent once adjusted for the impact of firm size.

F. Risk Premium Approach

18 **Q. Please briefly describe the risk premium method.**

19 A. The risk premium method of estimating investors’ required rate of return
20 extends to common stocks the risk-return tradeoff observed with bonds. The cost of equity
21 is estimated by first determining the additional return investors require to forgo the relative
22 safety of bonds and to bear the greater risks associated with common stock, and by then

²⁶ *Mont. Pub. Serv. Comm’n*, Order No. 7575c at P114 (Sept. 26, 2018).

²⁷ *Pre-Filed Direct Testimony of Anthony J. Ornelas*, Docket No. 30011-97-GR-17, (May 1, 2018) at 52-53.

²⁸ *Direct Testimony of Marlon F. Griffing, PH.D.*, Docket No. 17-071-U, (May 29, 2018) at 33-35.

1 adding this equity risk premium to the current yield on bonds. Like the DCF model, the risk
2 premium method is capital market oriented. However, unlike DCF models, which indirectly
3 impute the cost of equity, risk premium methods directly estimate investors' required rate of
4 return by adding an equity risk premium to observable bond yields.

5 **Q. Is the risk premium approach a widely accepted method for estimating**
6 **the cost of equity?**

7 A. Yes. The risk premium approach is based on the fundamental risk-return
8 principle that is central to finance, which holds that investors will require a premium in the
9 form of a higher return in order to assume additional risk. This method is routinely
10 referenced by the investment community and in academia and regulatory proceedings, and
11 provides an important tool in estimating a fair ROE for Avista.

12 **Q. How do you implement the risk premium method?**

13 A. I base my estimates of equity risk premiums for electric utilities on surveys of
14 previously authorized ROEs. Authorized ROEs presumably reflect regulatory commissions'
15 best estimates of the cost of equity, however determined, at the time they issued their final
16 order. Moreover, allowed ROEs are an important consideration for investors and have the
17 potential to influence other observable investment parameters, including credit ratings and
18 borrowing costs. Thus, when considered in the context of a complete and rigorous analysis,
19 this data provides a logical and frequently referenced basis for estimating equity risk
20 premiums for regulated utilities.

21 **Q. Is it circular to consider risk premiums based on authorized returns in**
22 **assessing a fair ROE for Avista?**

23 A. No. In establishing authorized ROEs, regulators typically consider the results
24 of alternative market-based approaches, including the DCF model. Because allowed risk

1 premiums consider objective market data (*e.g.*, stock prices, dividends, beta, and interest
2 rates), and are not based strictly on past actions of other regulators, this mitigates concerns
3 over any potential for circularity.

4 **Q. How do you calculate the equity risk premiums based on allowed**
5 **returns?**

6 A. The ROEs authorized for electric utilities by regulatory commissions across
7 the U.S. are compiled by S&P Global Market Intelligence and published in its *RRA*
8 *Regulatory Focus* report. On page 3 of Exh. AMM-11, the average yield on long-term
9 public utility bonds is subtracted from the average allowed rate of return on common equity
10 for electric utilities to calculate equity risk premiums for each year between 1974 and
11 2020.²⁹ Over this 47-year period, these equity risk premiums for electric utilities average
12 3.82 percent, and the yield on public utility bonds average 7.99 percent.

13 **Q. Is there any capital market relationship that must be considered when**
14 **implementing the risk premium method?**

15 A. Yes. There is considerable evidence that the magnitude of equity risk
16 premiums is not constant and that equity risk premiums tend to move inversely with interest
17 rates. In other words, when interest rate levels are relatively high, equity risk premiums
18 narrow, and when interest rates are relatively low, equity risk premiums widen. The
19 implication of this inverse relationship is that the cost of equity does not move as much as,
20 or in lockstep with, interest rates. Accordingly, for a 1 percent increase or decrease in
21 interest rates, the cost of equity may only rise or fall some fraction of 1 percent. Therefore,
22 when implementing the risk premium method, adjustments may be required to incorporate

²⁹ Yield averages reported by Moody's are for seasoned bonds with a remaining maturity of 20 years or more.

1 this inverse relationship if current interest rate levels diverge from the average interest rate
2 level represented in the data set.

3 **Q. Has this inverse relationship been documented in the financial research?**

4 A. Yes. There is considerable empirical evidence that when interest rates are
5 relatively high, equity risk premiums narrow, and when interest rates are relatively low,
6 equity risk premiums are greater. This inverse relationship between equity risk premiums
7 and interest rates has been widely reported in the financial literature. As summarized by
8 New Regulatory Finance:

9 Published studies by Brigham, Shome, and Vinson (1985), Harris (1986),
10 Harris and Marston (1992, 1993), Carelton, Chambers, and Lakonishok
11 (1983), Morin (2005), and McShane (2005), and others demonstrate that,
12 beginning in 1980, risk premiums varied inversely with the level of interest
13 rates – rising when rates fell and declining when rates rose.³⁰

14 Other regulators have also recognized that, while the cost of equity trends in the
15 same direction as interest rates, these variables do not move in lock-step.³¹ This relationship
16 is illustrated in the figure on page 4 of Exh. AMM-11. As shown there, the “R-squared”
17 value³² for the equity risk premium-utility bond interest rate relationship is approximately
18 0.9. This is an extremely high score and indicates a strong inverse relationship between
19 equity risk premiums and utility bond interest rates.

20 **Q. What are the implications of this relationship under current capital**
21 **market conditions?**

³⁰ Roger A. Morin, *New Regulatory Finance*, Pub. Util. Reports (2006) at 128.

³¹ See, e.g., California Public Utilities Commission, Decision 08-05-035 (May 29, 2008); Entergy Mississippi Formula Rate Plan FRP-7, https://www.google.com/url?sa=t&rct=j&q=&esrc=s&source=web&cd=&ved=2ahUKEwiLs4Sy67nsAhVKHqwkHddgAlwQFjABegQIBRAC&url=https%3A%2F%2Fcdn.entropy-mississippi.com%2Fuserfiles%2Fcontent%2Fprice%2Ftariffs%2Feml_frp.pdf&usg=AOvVaw1vyc6J_1IccZshzpfCtD0v (last visited Oct. 16, 2020); Opinion No. 531, 147 FERC ¶ 61,234 at P 147 (2014).

³² R-squared (R^2) is a statistical measure that represents the proportion of the variance for a dependent variable (in this case, the equity risk premium level) that is explained by an independent variable (utility bond yields) in a regression model.

1 A. Current bond yields are lower than those prevailing over the risk premium
 2 study periods. Given that equity risk premiums move inversely with interest rates, these
 3 lower bond yields also imply an increase in the equity risk premium that investors require to
 4 accept the higher uncertainties associated with an investment in utility common stocks
 5 versus bonds. In other words, higher required equity risk premiums offset the impact of
 6 declining interest rates on the ROE. This relationship is illustrated in the figure below,
 7 which is based on three-year rolling averages for the utility bond yields and risk premiums
 8 shown on page 3 of Exh. AMM-11.

9
10

**FIGURE 2
INVERSE RELATIONSHIP**

11 **Q. What cost of equity is implied by the risk premium method using surveys**
12 **of allowed ROEs?**

13 A. Because risk premiums move inversely with interest rates and current bond
14 yields are significantly lower than the average over the study period, it is necessary to adjust

1 the average equity risk premium over the study period to reflect the impact of changes in
2 bond yields. Based on the regression output between the interest rates and equity risk
3 premiums displayed on page 4 of Exh. AMM-11, the equity risk premium for electric
4 utilities increased approximately 43 basis points for each percentage point drop in the yield
5 on average public utility bonds. As illustrated on page 1 of Exh. AMM-11, with the yield on
6 average public utility bonds for the six months ending November 2021 being 3.06 percent,
7 this implied a current equity risk premium of 5.92 percent for electric utilities. Adding this
8 equity risk premium to the yield on Baa utility bonds of 3.26 percent produces a current cost
9 of equity of 9.18 percent.

10 Q. What cost of equity estimate is produced by the risk premium approach after
11 incorporating forecasted bond yields?

12 A. As shown on page 2 of Exh. AMM-11, incorporating a forecasted yield for
13 2023-2024 and adjusting for changes in interest rates since the study period implies an
14 equity risk premium of 5.88 percent, which is less than the current equity risk premium.
15 This lower equity risk premium is consistent with the inverse relationship I described above.
16 Adding this equity risk premium to the average implied yield on long-term Baa public utility
17 bonds for 2023-2024 of 3.66 percent results in an implied cost of equity of 9.24 percent.

G. Expected Earnings Approach

18 Q. **What other analyses do you conduct to estimate the cost of common**
19 **equity?**

20 A. I also evaluate the cost of common equity using the expected earnings
21 method. Reference to rates of return available from alternative investments of comparable
22 risk can provide an important benchmark in assessing the return necessary to assure
23 confidence in the financial integrity of a firm and its ability to attract capital. This expected

1 earnings approach is consistent with the economic underpinnings for a fair rate of return
2 established by the U.S. Supreme Court in *Bluefield*³³ and *Hope*.³⁴ Moreover, it avoids the
3 complexities and limitations of capital market methods and instead focuses on the returns
4 earned on book equity, which are readily available to investors.

5 **Q. What economic premise underlies the expected earnings approach?**

6 A. The simple, but powerful concept underlying the expected earnings approach
7 is that investors compare each investment alternative with the next best opportunity. If the
8 utility is unable to offer a return similar to that available from other opportunities of
9 comparable risk, investors will become unwilling to supply the capital on reasonable terms.
10 For existing investors, denying the utility an opportunity to earn what is available from other
11 similar risk alternatives prevents them from earning their opportunity cost of capital. Such
12 an outcome would violate the *Hope* and *Bluefield* standards and undermine the utility's
13 access to capital on reasonable terms.

14 **Q. How is the expected earnings approach typically implemented?**

15 A. The traditional comparable earnings test identifies a group of companies that
16 are believed to be comparable in risk to the utility. The actual earnings of those companies
17 on the book value of their investment are then compared to the allowed return of the utility.
18 While the traditional comparable earnings test is implemented using historical data taken
19 from the accounting records, it is also common to use projections of returns on book
20 investment, such as those published by recognized investment advisory publications (*e.g.*,
21 Value Line). Because these returns on book value equity are analogous to the allowed return

³³ *Bluefield Water Works & Improvement Co. v. Pub. Serv. Comm'n*, 262 U.S. 679 (1923) ("*Bluefield*").

³⁴ *Federal Power Comm'n v. Hope Natural Gas Co.*, 320 U.S. 391 (1944) ("*Hope*").

1 on a utility's rate base, this measure of opportunity costs results in a direct, "apples to
2 apples" comparison.

3 Moreover, regulators do not set the returns that investors earn in the capital markets,
4 which are a function of dividend payments and fluctuations in common stock prices, both of
5 which are outside their control. Regulators can only establish the allowed ROE, which is
6 applied to the book value of a utility's investment in rate base, as determined from its
7 accounting records. This is directly analogous to the expected earnings approach, which
8 measures the return that investors expect the utility to earn on book value. As a result, the
9 expected earnings approach provides a meaningful guide to ensure that the allowed ROE is
10 similar to what other utilities of comparable risk will earn on invested capital.

11 This expected earnings test does not require theoretical models to indirectly infer
12 investors' perceptions from stock prices or other market data. As long as the proxy
13 companies are similar in risk, their expected earned returns on invested capital provide a
14 direct benchmark for investors' opportunity costs that is independent of fluctuating stock
15 prices, market-to-book ratios, debates over DCF growth rates, or the limitations inherent in
16 any theoretical model of investor behavior.

17 **Q. What rates of return on equity are indicated for utilities based on the**
18 **expected earnings approach?**

19 A. For the firms in the Utility Group, the year-end returns on common equity
20 projected by Value Line over its forecast horizon are shown on Exh. AMM-12. As I
21 explained earlier in my discussion of the $br+sv$ growth rates used in applying the DCF
22 model, Value Line's returns on common equity are calculated using year-end equity

1 balances, which understates the average return earned over the year.³⁵ Accordingly, these
2 year-end values are converted to average returns using the same adjustment factor discussed
3 earlier and developed on Exh. AMM-8. As shown on Exh. AMM-12, Value Line's
4 projections for the Utility Group suggest an average ROE of approximately 11.0 percent.

II. NON-UTILITY BENCHMARK

5 **Q. What is the purpose of this section of your testimony?**

6 A. This section presents the results of my DCF analysis applied to a group of
7 low-risk firms in the competitive sector, which I refer to as the "Non-Utility Group." This
8 analysis is not directly considered in arriving at my recommended ROE range of
9 reasonableness; however, it is my opinion that this is a relevant consideration in evaluating a
10 fair and reasonable ROE for the Company

11 **Q. Do utilities have to compete with non-regulated firms for capital?**

12 A. Yes. The cost of capital is an opportunity cost based on the returns that
13 investors could realize by putting their money in other alternatives. Clearly, the total capital
14 invested in utility stocks is only the tip of the iceberg of total common stock investment, and
15 there are a plethora of other enterprises available to investors beyond those in the utility
16 industry. Utilities must compete for capital, not just against firms in their own industry, but
17 with other investment opportunities of comparable risk. Indeed, modern portfolio theory is
18 built on the assumption that rational investors will hold a diverse portfolio of stocks, not just
19 companies in a single industry.

³⁵ For example, to compute the annual return on a passbook savings account with a beginning balance of \$1,000 and an ending balance of \$5,000, the interest income would be divided by the average balance of \$3,000. Using the \$5,000 balance at the end of the year would understate the actual return.

1 **Q. Is it consistent with the *Bluefield* and *Hope* cases to consider investors’**
2 **required ROE for non-utility companies?**

3 A. Yes. The cost of equity capital in the competitive sector of the economy form
4 the very underpinning for utility ROEs because regulation purports to serve as a substitute
5 for the actions of competitive markets. The Supreme Court has recognized that it is the
6 degree of risk, not the nature of the business, which is relevant in evaluating an allowed
7 ROE for a utility. The *Bluefield* case refers to “business undertakings attended with
8 comparable risks and uncertainties.” It does not restrict consideration to other utilities.
9 Similarly, the *Hope* case states:

10 By that standard, the return to the equity owner should be commensurate with
11 returns on investments in other enterprises having corresponding risks.³⁶

12 As in the *Bluefield* decision, there is nothing to restrict “other enterprises” solely to the
13 utility industry.

14 **Q. Does consideration of the results for the Non-Utility Group make the**
15 **estimation of the cost of equity using the DCF model more reliable for Avista?**

16 A. Yes. The estimates of growth from the DCF model depend on analysts’
17 forecasts. It is possible for utility growth rates to be distorted by short-term trends in the
18 industry, or by the industry falling into favor or disfavor by analysts. Such distortions could
19 result in biased DCF estimates for utilities. Because the Non-Utility Group includes low
20 risk companies from many industries, it helps to insulate against any possible distortion that
21 may be present in the results for a particular sector.

22 **Q. What criteria do you apply to develop the Non-Utility Group?**

23 A. The comparable risk proxy group is composed of those U.S. companies
24 followed by Value Line that:

³⁶ *Federal Power Comm’n v. Hope Natural Gas Co.*, 320 U.S. 391 (1944) (“*Hope*”).

- 1) pay common dividends;
- 2) have a Safety Rank of “1”;
- 3) have a Financial Strength Rating of “A” or greater;
- 4) have a beta of less than 1.00; and
- 5) have investment grade credit ratings from S&P and Moody’s.

Q. How do the overall risks of this Non-Utility Group compare with the Utility Group and Avista?

A. Table 3 compares the Non-Utility Group with the Utility Group and Avista across the measures of investment risk discussed earlier:

**TABLE 3
COMPARISON OF RISK INDICATORS**

	<u>Value Line</u>				
	<u>S&P</u>	<u>Moody's</u>	<u>Safety Rank</u>	<u>Financial Strength</u>	<u>Beta</u>
Non-Utility Group	A	A2	1	A++	0.80
Utility Group	BBB+	Baa2	2	A	0.91
Avista Corp.	BBB	Baa2	2	B++	0.95

As shown above, all of the risk indicators for the Non-Utility Group suggest less risk than for the Utility Group and Avista.

The companies that make up the Non-Utility Group are representative of the pinnacle of corporate America. These firms, which include household names such as Coca-Cola, Procter & Gamble, and Walmart, have long corporate histories, well-established track records, and exceedingly conservative risk profiles. Many of these companies pay dividends on a par with utilities, with the dividend yield for the group averaging 2.2 percent. Moreover, because of their significance and name recognition, these companies receive intense scrutiny by the investment community, which increases confidence that published

1 growth estimates are representative of the consensus expectations reflected in common stock
2 prices.

3 **Q. What are the results of your DCF analysis for the Non-Utility Group?**

4 A. I apply the DCF model to the Non-Utility Group using the same analysts EPS
5 growth projections described earlier for the Utility Group, with the results being presented in
6 Exh. AMM-14. As summarized in Table 4, below, application of the constant growth DCF
7 model resulted in the following cost of equity estimates:

8 **TABLE 4**
9 **DCF RESULTS – NON-UTILITY GROUP**

<u>Growth Rate</u>	<u>Average</u>
Value Line	10.2%
IBES	10.2%
Zacks	10.8%

10 As discussed earlier, reference to the Non-Utility Group is consistent with
11 established regulatory principles. Required returns for utilities should be in line with those
12 of non-utility firms of comparable risk operating under the constraints of free competition.
13 Because the actual cost of equity is unobservable, and DCF results inherently incorporate a
14 degree of error, cost of equity estimates for the Non-Utility Group provide an important
15 benchmark in evaluating a fair and reasonable ROE for Avista.
